TOWARDS A REVOLUTIONARY APPROACH TO HEALTH

Sometime during the last year, some of us working in the field of health realised that there was a need for a separate periodical which would analyse and discuss health issues from a broadly marxist perspective. *Socialist Health Review* (SHR) is being published with a conviction that it would fulfil this need by acting as a platform for discussion and helping the propagation and development of a marxist analysis of health (i. e. determinants and dynamics of health and disease) and medicine (i. e. medical technology as well as systems of medical care).

It may well be asked as to what the necessity is of a separate periodical when there exists a plethora of journals devoted to both marxism as well as health. Since the 70's various groups and individuals with different ideological positions have been working in the field of health. Many health workers, and doctors have, through their exposure to people's struggles to change the oppressive social reality, been attracted to the left movement and specifically to marxism. They have come to realise the need for a substantial, radical critique of health and medicine. Moreover, most marxist doctors, health workers in India are more or less ignorant about marxist analysis of health and medicine. But with the growth of the health and science movements in India, we have all increasingly felt the need to know and to develop a marxist analysis of health and medicine. At the same time, many political activists and social workers too, as a result of their exposure to health problems have realised the relevance of such an exercise. The growth of people's science movements in the country (e. g. Lok Vignyan Sangathana in Maharashtra, Kerala Shastra Sahitya Parishad, Kerala) has also contributed to this awareness. Activists of these movements have been exposed to, and have also challenged the existing health and medical care system and consequently, have realised the need for analysing them. All these developments have resulted in generating an awareness amongst medicos, social workers and political activists of the relevance of radical health praxis to the left movement.

Such an analysis not only advances the general theory of radical political action — which we believe to be critical for any fundamental change in the health situation — but also provides a specific theoretical direction for radical health action. As of today, in India, there is little understanding of various theoretical questions related to health and medicine: the political economy; the bourgeois, male dominated ideological positions; underlying positivist outlook etc. As argued earlier, the need to develop such a theory through mutual discussions and debates does exist. Given the geographical distances that separate us, the best solution the situation offers is a periodical.

Now, it could be argued that existing forums like the *Medico Friends Circle Bulletin* could be utilised for this purpose. We feel that periodicals like these have played and will continue to play the very purposeful role of exposing socially conscious individuals to concrete alternatives and in developing a radical democratic critique of health and medicine. But, they have an inherent limitation in that the divergent or sometimes equivocal ideological commitments of their readership makes a discussion from a particular ideological standpoint, especially the marxist one, a a futile affair. Even when it does take place, much of the rigour is lost.

Periodicals like the *EPW, and Social Scientist*, while publishing marxist analyses of society have an obvious limitation in that they cover a wide field and therefore, they cannot become platforms for continuous debates on health and medicine only.

This in short, is the *raison d'etre* of a separate periodical devoted to propagating and developing a marxist theory of health and medical care, a task which SHR proposes to undertake.

Editorial Policy

As stated earlier SHR will function as a forum for propagating and developing a marxist approach to health and medicine. By a marxist approach we mean that analytical approach which takes a historical materialist and dialectical view of the health of a people and the medical care system in a given social order. From a marxist standpoint, health can be considered as a part and consequence of economic, political and socio-cultural development of society. The problems of health and the health care system reflect the problems of the dialectic of production forces and production relations and the broader social order based on it. They cannot be separated from the problems of this broader social order. As health care and medicine operate today

through public institutions and private clinics, insights into who controls them and how this control operates is significant for such an approach. The role played by these institutions in social control and reinforcement of the existing ideology would be the focus of such an analytical approach.

The editorial policy will aim to present the various currents which have contributed to the development of such an approach to health and medicine. It must be emphasised here that in our opinion, there does not exist one single, marxist analysis — an all correct perfect 'line' so to say, of health and medicine. Only a continuous interaction at the level of praxis amongst the different trends within the marxist movement can lead to the process of distilling the truth. Therefore, SHR will contain articles and viewpoints reflecting this diversity in marxist thought albeit with the limitations spelt out later.

We believe that the women's health movement has added a new dimension to the critique of the organisation and contents of medicine. Therefore, SHR will also contain reflections mainly of the marxist-feminist viewpoint — and sometimes even of the non-marxist ones — directed towards the exposure of the ideological substructure of the developments in medicine.

The Illichian trend is characterised by its criticism of the bureaucratising and centralising tendency of modern health care systems, while overlooking the class basis of these tendencies. It has nevertheless contributed to the critical views on medical care in bourgeois society. This is despite the fact that this criticism arises from within the bourgeois ideological standpoint. Occasionally, this current may, too, find a place in this periodical.

These three points of view have one common direction : they oppose the existing ideological position dominant in the sociology of medicine, one rooted in the structural-functional school. This school assumes the neutrality of medicine (and all sciences) and examines the health care systems without reference to the character of society. It refrains from a political analysis of the medical system and places great emphasis on the social factors affecting health without enquiring into the root cause of their existence, the economic base of society.

It is this commonality that forms the justification for including them together in this periodical.

Of late, there has been a spurt in the literature on the marxist analysis of health and medicine in the US and other western countries. Many of us are not exposed to these, as not all of us have an easy access to the relevant reading material. Therefore, the periodical will contain reproductions of such articles with introductory comments whenever necessary.

In order to develop a 'concrete analysis of the concrete situation', SHR would encourage publishing of original articles pertaining to the Indian situation and debates and comments thereupon. We hope that in a short time, original articles will form the bulk of the periodical.

Keeping in view the development of the Indian marxist movement in general, the following, in our view must be strictly observed while writing original articles:

1. The central propositions of the articles must be worked out logically with supporting empirical evidence.

2. Subsidiary propositions and other general statements regarding the economic and political situation, for example, the nature of mode of production in India, strategies of revolution etc. must have a direct bearing on the central propositions. This is imperative in order to avoid a debate on these issues on the pages of this periodical (though these are obviously essential for political activists) and to prevent irrelevant generalisations.

In addition to these main articles, SHR will also contain features like news, book reviews, field reports, letters to the editor and so on.

SHR's relation to the left movement : SHR being a periodical devoted to theoretical aspects of health and medicine does not propose to become an action-oriented periodical in the sense of an organiser of an action group. We believe that the formulation and clarification of these theoretical issues are essential for successful, politically relevant action and in that way the periodical would facilitate effective health action in the manner after journals like *Monthly Review* or *Social Scientist*.

We feel that the very fact of the need for such a periodical having been felt indicates that the health movement within the broad left movement has reached a stage of maturity though not of a level necessitating a formal organisation. But, this does not and cannot, preclude the possibility of formation of such an organisation in future.

At present, SHR would contribute to the general fund of marxist analyses which is particularly deficient in this respect in India. We consider this

deficiency, even mistakes and distortions within the left movement, as our deficiency, mistakes and distortions. And if they have to be criticised — which of course, they need to be — the criticism should be a self-criticism, with a view to improve upon the past and the present so that the movement proceeds with unity, strength and on a politically correct path towards its historical goal. Let me make it clear that we do not stand for a goody-goody, come-what may-we-shall-stay-united type of left unity but we certainly oppose the kind of sectarianism that leads us to mutual mud-slinging while the enemy without goes unexposed and unchallenged.

In this issue

To drive home the point made above regarding the relationship of the problems of health and medicine with those of society in general, we open our publication with an overview of Health and Politics.

In any class society, and by the same logic, in bourgeois society, every institution is controlled by a class/classes to further its/their own interests against certain other class/classes. Under the hegemony of the bourgeois, health has become a commodity and consequently, there has been a proliferation of health 'producing' institutions and businesses. And according to the same logic, they are controlled by the bourgeoisie to perpetuate and justify their hegemony. The articles appearing in this inaugural issue set the keynote of the marxist approach to health and medicine.

Howard Waitzkin in his article (a reproduction) *A Marxist View of Medical Care* reviews marxist literature on health and medicine. The article shows how the present health system reflects the class structure of captalist society and how this class structure manifests itself in various ways: control over health institutions, stratification of health workers, health policy etc. He goes on further to show the penetration of monopoly capital into the 'medical-industrial complex'. The article deals briefly with the concepts of historical materialist epidemiology focussing on the effects of economic cycles, social stress, working conditions and sexism on health.

Amar Jesani and Padma Prakash in their article *Political Economy of Health Care in India* select one aspect of the relationship of health and politics and put it in the Indian perspective. They lucidly trace the connection between the economic base of Indian society and health system.

Binayak Sen's article focusses on areas which have either been dealt with only superficially in Waitzkin's article or not at all.

Anant Phadke introduces the book *Cultural Crisis of Modern Medicine* edited by John Ehrenreich, with his critical comments thereupon.

From this issue onwards, each issue will be devoted to one aspect of health and medicine.

An Appeal

Our reader friends would agree that building up a platform for the task envisaged by SHR requires a lot of collective effort. We appeal to our comrades to accept this challenge and extend their fraternal support to this venture. There are several ways in which SHR could be helped:

As with any other publication of this type, SHR too, badly needs financial support. Although several friends have promised to collect funds, the total amount would just be barely sufficient for the first few issues only. Financial support for SHR could be enlisted by either enrolling subscribers or collecting donations.

In case, you are unable to contact a person whom you know would be interested, his/her address could be sent to us. We would send the first issue with an appeal for subscription/donation.

Original articles or reproductions including theoretical analyses, relevant research papers, reports of alternatives in health care, reports of health care in post-revolutionary societies, book reviews etc. could be sent to us for publication. (See back cover).

SHR is a platform of discussion. Hence opinions of the readers regarding the production of the periodical material published and of course, the views presented here are welcome — nay, necessary for the growth of this periodical.

If one goes by the enthusiastic response we have received so far it would not be too much to hope that the Socialist Health Review in a short time, would become a leading theoretical organ of the growing health movement within our country and would contribute significantly to the general fund of marxist literature.

Dhruv Mankad

A MARXIST VIEW OF MEDICAL CARE

howard waitzkin

Marxist studies of medical care emphasise political power and economic dominance in capitalist society. Although historically the marxist paradigm went into eclipse during the early twentieth century, the field has developed rapidly during recent years. The health system mirrors the society's class structure through control over health institutions, stratification of health workers, and limited occupational mobility into health professions. Monopoly capital is manifest in the growth of medical centres, financial penetration by large corporations, and the "medical-industrial complex." Health policy recommendations reflect different interest groups' political and economic goals. The state's intervention in health care generally protects the capitalist economic system and the private sector. Medical ideology helps maintain class structure and patterns of domination. Comparative international research analyses the effects of imperialism, changes under socialism, and contraditions of health reform in capitalist societies. Historical materialist epidemiology focuses on economic cycles, social stress, illness-generating conditions of work, and sexism. Health praxis, the disciplined uniting of study and action, involves advocacy of "nonreformist reforms" and concrete types of political struggle.

This review surveys the rapidly growing marxist literature in medical care. The marxist viewpoint questions whether major improvements in the health system can occur without fundamental changes in the broad social order. One thrust of the field, an assumption also accepted by many non-marxists, is that the problems of the health system reflect the problems of our larger society and cannot be separated from those problems.

Marxist analyses of health care have burgeoned in the United States during the past decade. However, it is not a new field. Its early history and the reasons for its slow growth until recently deserve attention.

Historical Development of the Field

The first major marxist study of health care was Engel's *The Condition of the Working Class in England* (1), originally published in 1845, three years before Engels coauthored with Marx *'The Communist Manifesto'* (2). This book described the dangerous working and housing conditions that create ill health. In particular, Engles traced such diseases as tuberculosis, typhoid and typhus to malnutrition, inadequate housing, contaminated water supplies and overcrowding. Engels' analysis of health care was part of a broader study of working class conditions under capitalist industrialisation. But this treatment of health problems was to have a profound effect on the emergence of social medicine in Western Europe, particularly the work of Rudolf Virchow.

Virchow's pioneering studies in infectious disease, epidemiology, and "social medicine" (a term Virchow popularised in Western Europe) appeared with great rapidity after the publication of Engels' book on the English working class. Virchow himself acknowledged Engels' influence on his thought. In 1847, at the request of the Prussian government, Virchow investigated a severe typhus epidemic in a rural area of the country. Based on this study, Virchow recommended a series of profound economic, political, and social changes that included increased employment, better wages, local autonomy in government, agricultural cooperatives, and a more progressive taxation structure. Virchow advocated no strictly medical solutions, such as more clinics or hospitals. Instead, he saw the origins of ill health in social problems. The reasonable approach to the problem of epidemics, then, was to change the conditions that permitted them to occur. (4,5.)

During this period Virchow was committed to combining his medical work with political activities. In 1848 he joined the first major working-class revolt in Berlin. During the same year he strongly supported the short-lived revolutionary efforts of the Paris Commune (6-8). In his scientific investigations and in his political practice, Virchow expressed two overriding themes. First, the origin of disease is multifactorial. Among the most important factors in causation are the material conditions of people's everyday lives. Second, an effective health-care system cannot limit itself to treating the pathophysiologic disturbances of individual patients. Instead, to be successful, improvements in the health care system must coincide with fundamental economic, political and social changes. The latter changes often impinge on the privileges of wealth and power enjoyed by the dominant classes of society and thus, encounter resistance. Therefore, in Virchow's view, the responsibilities of the medical scientist frequently extend to direct political action.

After the revolutionary struggles of the late 1840s suffered defeat, Western European governments heightened their conservative and often

repressive social policies. Marxist analysis of health-care entered a long period of eclipse. With the onset of political reaction, Virchow and his colleagues turned to relatively uncontroversial research in laboratories and to private practice.

During the late nineteenth century, with the work of Ehrlich, Koch, Pasteur, and other prominent bacteriologists, germ theory gained ascendancy and created a profound change in medicine's diagnostic and therapeutic assumptions. A unifactorial model of disease emerged. Medical scientists searched for organisms that cause infections and single lesions in non-infectious disorders. The discoveries of this period undeniably improved medical practice. Still, as numerous investigators have shown, the historical importance of these discoveries has been overrated. For example, the major declines in mortality and morbidity from most infectious diseases preceded rather than followed the isolation of specific etiologic agents and the use of antimicrobial therapy. In Western Europe and the United States, improved outcomes in infections occurred after the introduction of better sanitation, regular source of nutrition, and other broad environmental changes. In most cases, improvements in disease patterns antedated the advances of modern bacteriology (9-17).

Why did the unifactorial perspective of germ theory achieve such prominence ? And why have the investigational techniques that assume specific etiology and therapy retained a nearly mythic character in medical science and practice to the present day ? A serious historical reexamination of early twentieth century medical science, which attempts to answer these questions, has begun only in the past few years. Some preliminary explanations have emerged; they focus on events that led to and followed publication of the Flexner Report (18).

The Flexner Report has been held in high esteem as the document that helped change modern medicine from quackery to responsible practice. One underlying assumption of the report was the laboratory based scientific medicine, oriented especially to the concepts and methods of European bacteriology, produced higher quality and more effective medical practice. Although the comparative effectiveness of various medical traditions (including homoeopathy, traditional folk healing, chiropractic, and so forth) had never been subjected to systematic test, the report argued that medical schools not oriented to scientific medicine fostered mistreatment of the public. The report called for the closure or restructuring of schools that were not equipped to teach laboratory-based medicine. The report's repercussions were swift and dramatic. Scientific, laboratory-based medicine became the norm for medical education, practice, research and analysis.

Recent historical studies cast doubt on assumptions in the Flexner Report that have comprised the widely accepted dogma of the past half century. They also document the uncritical support that the report's recommendations received from parts of the medical profession and the large private philanthropies (19-27). At least partly because of these events, the marxist orientation in medical care remained in eclipse.

Although some of Virchow's works gained recognition as classics, the multifactorial and politically oriented model that guided his efforts has remained largely buried. Without doubt, marxist perspectives had important impacts on health care outside Western Europe and the Untied States. For example, Lenin applied these perspectives to the early construction of the Soviet health system (28). Salvador Allende's treatise on the political economy of health care, written while Allende was working as a public health physician exerted a major influence on health programmes in Latin America (29). The Canadian surgeon, Norman Bethune, contributed analyses of tuberculosis and other diseases, as well as direct political involvement, that affected the course of post-revolutionary Chinese medicine (30-32). Che Guevara's analysis of the relations among politics, economics and health care — emerging partially from his experience as a physician — helped shape the Cuban medical system (33,34).

Perhaps reflecting the political ferment of the late 1960s and widespread dissatisfaction with various aspects of modern health systems (35), serious marxist scholarship of health care has grown rapidly. Recent work began in Western Europe (36,37) and spread to the United States with the publication of Kelman's path-breaking article in 1971 (38). The following sections of this review focus on current areas of research and analysis.

Class Structure

Marx's definitions of social class emphasised the social relations of economic production. He noted that one group of people, the capitalist class or bourgeoisie, own or control (or both) the means of production : the machines, factories, land, and raw materials necessary to make products for the market. The working class or proletariat, who do not own or control the means of production, must sell their labor for a wage. But the value of the product that workers

produce is always greater than their wage (39). Workers must give up their product to the capitalist; by losing control of their own productive process, workers become subjectively "alienated" from their labor (40). "Surplus value", the difference between the wage paid to workers and the value of the product they create, is the objective basis of the capitalist's profit. Surplus value also is the structural source of "exploitation"; it motivates the capitalist to keep wages low, to change the work process (by automation and new technologies, close supervision, lengthened work day or overtime, speed-ups and dangerous working conditions), and to resist workers' organized attempts to gain higher wages or more control in the workplace (41).

Although they acknowledge the historical changes that have occurred since Marx's time (52-51), recent marxist studies have reaffirmed the presence of highly stratified class structures in advanced capitalist societies and Third World nations (52-54). Another topic of great interest is the persistence or reappearance of class structure, usually based on expertise and professionalism, in countries where socialist revolutions have taken place (55,56); a later section of this review focuses on that problem. These theoretical and empiricial analyses show that relations of economic production remain a primary basis of class structure and a reasonable focus of strategies for change (57-59).

Miliband's (59) definitions of social class have provided a framework for marxist research on class structure in the health system. This research has shown that the health system mirrors the class structure of the broader society (60-63).

The "corporate class" includes the major owners and controllers of wealth. They comprise 1% of the population and own 80% of all corporate stocks and state and local government bonds; their median annual income (1975 estimates) is 114000 dollars to 142000 dollars. The "working class", at the opposite end of the scale, makes up 49% of the population. It is composed of annual laborers, service workers, and farm workers, who generally earn 8500 dollars per year or less. Between these polar classes are the "upper middle class" (professionals like doctors, lawyers, and so forth, comprising 14% of the population and earning about 25600 dollars; and middle-level business executives, 6% of the population and earning about 22700 (dollars; and the "lower middle class" (shopkeepers, self-employed people, craftsmen, artisans, comprising 7% of the population, earning about 12000 dollars and clerical and sales workers, 23%of the population, earning about 9200 dollars per year). Although these definitions provide summary descriptions of a very complex social reality, they are useful in analysing manifestations of class structure in the health system.

Control over Health Institutions

Navarro (60-62) has documented the pervasive control that members of the corporate and upper middle classes exert within the policy-making bodies of American health institutions (Table 1). These classes predominate on the governing boards of private foundations in the health system, private and state medical teaching institutions, and local voluntary hospitals. Only on the boards of state teaching institutions and voluntary hospitals do members of the lower middle class or working class gain any appreciable representation; even there, the participation from these classes falls far below their proportion in the general population. Local research has documented corporate control of health institutions in many parts of the United States. Navarro has argued, based partly on these observations,

Table 1 : Social Class Composition of U.S. Labor Force and Boards of U.S. health institutions

	Class* (%)			
	Corporate	Upper middle	Lower middle	Working
U.S. labor force	1	20	30	49
Board members				
Foundations	70	30	—	—
Private medical teaching institutions	45	55	—	—
State medical teaching institutions	20	70	10	—
Voluntary hospitals	5	80	10	5

*See text for definitions : source, Navarro V; Social policy issues : an expalanation of the composition, nature, and functions of the present health sector of the United States. Bull NY Acad Med 51:199-234, 1975 (Reference 60).

that control over health institutions reflects the same patterns of class dominance that have arisen in other areas of American economic and political life.

Stratification within Health Institutions

As members of the upper middle class, physicians occupy the highest stratum among workers in health institutions. Composing 7% of the health labor force, physicians receive median net income (approximately 53900 dollars in 1975) that places them in the upper 5% of the income distribution of the United States. Under physicians and professional administrators are members of the lower middle class: nurses, physical and occupational therapists, and technicians. They make up 29% of the health labor force, are mostly women, and earn about 3500 dollars. At the bottom of institutional hierarchies are clerical workers, aides, orderlies, and kitchen and janitorial personnel, who are the working class of the health system. They have an income of about 700 dollars per year, represent 54% of the health labor force, and are 84% female and 30% black (60,63).

Recent studies have analysed the forces of professionalism, elitism, and specialisation that divide health workers from each other and prevent them from realising common interests. These patterns affect physicians (64), nurses (65, 66), and technical and service workers who comprise the fastest growing segment of the health labor force (67-72). Bureaucratisation, unionisation, state intervention, and the potential "proletarianisation" of professional health workers may alter future patterns of stratification (73).

Occupational Mobility

Class mobility into professional positions is quite limited. Investigations of physicians' class background in both Britain and the United States have shown a consistently small representation of the lower middle and working classes among medical students and practising doctors (23, 24, 74, 75). In the United States, historical documentation is available to trace changes in class mobility during the twentieth century. As Ziem (23, 24) has found despite some recent improvements for other disadvantaged groups like blacks and women, recruitment of working class medical students has been very limited since shortly after publication of the Flexner Report. In 1920, 12% of medical students came from working class families, and this percentage has stayed almost exactly the same until the present time.

Emergence of Monopoly Capital in the Health Sector

During the past century, economic capital has become more concentrated in a smaller number of companies, the monopolies. Monopoly capital has emerged in essentially all advanced capitalist nations, where the process of monopolisation has reinforced private corporate profit (70, 76, 78) (In a much different form monopolisation also occurs within socialist countries, where the state owns major capital assets and strongly limits private profitability). Monopoly capital has become a prominent feature of most capitalist health systems and is manifest in several ways.

Medical Centers

Since about 1910, a continuing growth of medical centers has occurred, usually in affiliation with universities. Capital is highly concentrated in these medical centres, which are heavily oriented to advanced technology. Practitioners have received training where technology is available and specialisation is highly valued. Partly as a result, health workers are often reluctant to practise in areas without easy access to medical centers. The nearly unrestricted growth of medical centers, coupled with their key role in medical education and the "technologic imperative" they encourage, has contributed to the maldistribution of health workers and facilities throughout the United States and within regions (38, 64).

Finance Capital

Monopoly capital also has been apparent in the position of banks, trusts and insurance companies, the largest profit making corporations under capitalism. For example, in 1973, the flow of health-insurance dollars through private insurance companies was 29 billion, about half of the total insurance sold. Among commercial insurance companies, capital is highly concentrated; about 60% of the health-insurance industry is controlled by the 10 largest insurers. Metropolitan Life and Prudential each control more than 30 billion dollars in assets, more than General Motors, Standard Oil of New Jersey, or International Telephone and Telegraph (60).

Finance capital figures prominently in current health reform proposals. Most plans for national health insurance would permit a continuing role for the insurance industry (79,80). Moreover, corporate investment in health maintenance organisations is increasing, under the assumption that national

health insurance, when enacted, will assure the profitability of these ventures (81.)

The "Medical-Industrial Complex"

The "military-industry complex" has provided a model of industrial penetration in the health system popularised by the term, "medical-industrial complex." Investigations by the Health Policy Advisory Center (82,83) and others have emphasised that the exploitation of illness for private profit is a primary feature of the health systems in advanced capitalist societies (64). Recent reports have criticised the pharmaceutical and medical equipment industries for advertising and marketing practices (82-86), price and patent collusion (87), marketing of drugs in the third world before their safety is tested (88-89), and promotion of expensive diagnostic and therapeutic innovations without controlled trials showing their effectiveness (13,90-91).

In this context, "cost-effectiveness" analysis has yielded useful appraisals of several medical practices and clinical decision-making, based in part on analysis of cost relative to effectiveness (94-100). Although recognising its contributions, marxist researchers have criticised the cost-effectiveness approach for asking some questions at the wrong level of analysis. This approach usually does not help clarify the overall dynamics of the health system that encourages the adoption of costly and ineffective technologic innovations. The practice evaluated by cost-effectiveness research generally emerges with the growth of monopoly capital in the health system. Costly innovations often are linked to the expansion of medical centers in the health system, and the promotion of new drugs, the penetration of finance capital and instrumentation by medical industries. Cost-effectiveness research and clinical decision analysis remain incomplete unless they consider broader political and economic trends that propel apparent irrationalities in the health system (90).

Interest Group Politics

Marx argued that class position and economic resources usually determine political power. He noted that the dominant economic class is composed of various groups with sometimes different interests. Although these groups unite when they face basic threats from the working class, their varying interests generate contradictions that can provide a focus for political strategy (101-105). In studies of health care, the analysis of interest group politics has focussed mainly on the United States and Great Britain (106-110). This approach demystifies the policy recommendations of many groups advocating health reforms. From this perspective these groups' viewpoints and proposals reflect largely their own political and economic interests, rather than simple concern for improving the health system.

Alford's (106,107) research delineates three major interest groups vying for power and finances. The professional monopolists include physicians, specialists, and health research workers in medical schools, universities, or private practice. The main consequence of their activity is a "continuous proliferation of programs and projects" that "provide a symbolic screen of legitimacy while maintaining power relationships" in the health system. 'Corporate rationalisers' are persons in top positions within health organisations: hospital administrators, medical school deans, and public health officials. The corporate rationalisers' overall effect, according to Alford, is to complicate and elaborate the bureaucratic structures of the health system. As third interest group is the diverse community population actually needing and affected by health services. Generally, Alford observes, this interest group's efforts are likely to fail. A high probability of cooptation means that leaders may assume symbolic positions on advisory boards or planning agencies, without real change in power structures.

The analysis of interest group politics has proved helpful in understanding local controversies such as attempts at community control of health institutions (111); conflicts among the governing boards, administrators and professional staffs of hospitals (112); failures in comprehensive health planning and regulation (113-116); and the expansion of medical institutions into urban residential areas (117-120). A similar perspective has led to a clearer picture of national health policy decisions, for example, those pertaining to cancer research and occupational health legislation (83-123).

These studies' implications for reform within the present system tend to be pessimistic. Because an "institutional and class structure creates and sustains the power of the professional monopolists and corporate rationalisers". Alford writes, "change is not likely without the presence of a social and political movement which rejects the legitimacy of the economic and social base of pluralist politics." (106).

The State and State Intervention

Because the state encompasses the major institutions of political power, its strategic importance is obvious. The state acts generally to repress

revolutionary social change or political action that threatens the present system in any fundamental way after socialist revolutions, the state apparatus must persist for a long time, but with greatly modified functions. Before focussing on health care, a brief overview and definition of the state are necessary.

Marx and Engels emphasised government's crucial role is protecting the capitalist economic system and the interests of the capitalist class. The famous homily of The Communist Manifesto, was "the state is the executive committee of the bourgeoisie" (2). Lenin (124) concluded that the capitalist class would intervene forcibly to block any electoral victory that seriously threatened the private enterprise system. More recent analysts have studied the structural patterns that preserve the dominance of the capitalist class over state policies (53, 59), the mechanisms by which the state eases the recurrent economic crises of the capitalist system (125-127); and ideologic techniques by which the state reinforces popular acquiescence (128, 129).

In this context the following definition, though limited by the subject's complexity, is appropriate. The state comprises the interconnected public institutions that act to preserve the capitalist economic system and the interests of the capitalist class. This definition includes the executive, legislative, and judicial branches of government, the military; and the criminal justice system all of which hold varying degrees of coercive power. It also encompasses relatively noncoercive institutions within the educational, public welfare, and health-care systems. Through such noncoercive institutions, the state offers services or conveys ideologic messages that legitimate the capitalist system. Especially in periods of economic crisis, the state can use these same institutions to provide public subsidisation of private enterprise.

The Private-Public Contradiction

Within the health system, the "public sector," as part of the state, operates through public expenditures and employs health workers in public institutions. The "private sector" is based in private practice and companies that manufacture medical products or control finance capital. Nations vary greatly in the private-public duality. In the United States, a dominant private sector coexists with an increasingly large public sector. The public sector is even larger in Great Britain and Scandinavia. In Cuba and China, the private sector essentially has been eliminated (64).

A general theme of Marxist analysis is that the private sector drains public resources and health workers' time, on behalf of private profit and to the detriment of patients using the public sector. This framework has helped to explain some of the problems that have arisen in such countries as Great Britain (75) and Chile (130, 131), where private sectors persisted after the enactment of national health services. In these countries, practitioners have faced financial incentives to increase the scope of private, practice, which they often have conducted within public hospitals or clinics. In the United States, the expansion of public payment programs such as Medicare and Medica aid has led to increased public subsidisation of private practice and private hospitals, as well as abuses of these programs by individual practitioners (64).

Similar problems have undermined other public health programs. These programs frequently have obtained finances through regressive taxation, placing low-income taxpayers at a relative disadvantage (79). Likewise, the deficiencies of the Blue Cross and Blue Shield insurance plans have derived largely from the failure of public regulatory agencies to control payments to practitioners and hospitals in the private sector (132). When enacted, national health insurance also would use public funds to reinforce and strengthen the private sector, by assuring payment for hospitals and individual physicians and possibly by permitting a continued role for commercial insurance companies (64, 80).

Throughout the United States the problems of the private-public contradition are becoming more acute. In most large cities, public hospitals are facing cutbacks, closure, or conversion to private ownership and control. This trend heightens low-income patients' difficulties in finding adequate health care (133). It also reinforces private hospitals' tendency to "dump" low-income patients to public institutions (134).

General Functions of the State within the Health System.

The state's functions in the health system have increased in scope and complexity. In the first place, through the health system, the state acts to legitimate the capitalist economic system based in private enterprise (135, 136). The history of public health and welfare programs shows that state expenditures usually increase during periods of social protest and decrease as unrest becomes less widespread (137, 138). Recently a Congressional committee summarised public opinion surveys that uncovered a profound level of dissatisfaction with

government and particularly with the role of business interests in government policies: " . . . citizens who thought something was 'deeply wrong' with their country had become a national majority ... And, for the first time in the ten years of opinion sampling by the Horris Survey, the growing trend of public opinion towards disenchantment with government swept more than half of all Americans with it" (139). Under such circumstances, the state's predictable response is to expand health and other welfare programs. These incremental reforms, at least in part, reduce the legitimacy crisis of the capitalist system by restoring confidence that the system can meet the people's basic needs. The cycles of political attention devoted to national health insurance in the United States appear to parallel cycles of popular discontent (135). Recent cutbacks in public health services to low-income patients follow the decline of social protest by low-income groups since the 1960s.

The second major function of the state in the health system is to protect and reinforce the private sector more directly. As previously noted most plans for national health insurance would permit a prominent role and continued profits for the private insurance industry, particularly in the administration of payments, record keeping, and data collection (64,80, 140). Corporate participation in new health initiatives sponsored by the state — including health maintenance organisations, preventive screening programs, computerised components of professional standards review organisations, algorithm and audiovisual aids for patient education programs — is providing major sources of expanded profit (81, 141).

A third (and subtler) function of the state is the reinforcement of dominant frameworks in scientific and clinical medicine that are consistent with the capitalist economic system and the suppression of alternative frameworks that might threaten the system. The United States government has provided generous funding for research on the pathophysiology and treatment of specific disease entities. As critics even within government have recognised, the disease-centered approach has reduced the level of analysis to the individual organism and, often inappropriately, has stimulated the search for unifactorial rather than multifactorial origin (142). More recently, analyses emphasising the importance in individul "life-style" as a cause of disease (14, 143, 144) have received prominent attention from state agencies in the United States and Canada (145, 146). Clearly individual differences in personal habits do affect health in all societies. On the other hand, the lifestyle argument, perhaps even more than the earlier emphasis on specific cause, obscures important sources of illness and disability in the capitalist work process and industrial environment; it also puts the burden of the health squarely on the individual, rather than seeking collective solutions to health problems (147, 148).

The issues that the state has downplayed in its research and development programs are worth noting. For example, based on available data, it is estimated that in Western industrialised societies environmental factors are involved in the etiology of approximately 80% of all cancer (149). In its session on "health and work in America," the American Public Health Association in 1975 produced an exhaustive documentation of common occupational carcinogens (150). A task force for the Department of Health, Education, and Welfare on *Work in America*, published by a nongovernment press in 1973, reported "In an impressive 15-year study of aging, the strongest predictor of longevity was work satisfaction. The second best predictor was overall 'happiness'... Other factors are undoubtedly important — diet, exercise, medical care, and genetic inheritance. But research findings suggest that these factors may account for only about 25 per cent of the risk factors in heart disease, the major cause of death... "(151). Such findings are threatening to the current organisation of capitalist production. They have received little attention or support from state agencies. A framework for clinical investigation that links disease directly to the structure of capitalism is likely to face indifference and active discouragement from the state.

Limits and Mechanisms of State Intervention

State intervention faces certain structural limits. Simply summarised, these limits restrict state intervention to policies and programs that will not conflict in fundamental ways with capitalist economic processes based on private profit, or with the concrete interests of the capitalist class during specific historical periods.

"Negative selection mechanisms" are forms of state intervention that exclude innovations or activities that challange the capitalist system (125, 126). For example, agencies of the state may enact occupational health legislation and enforcement regulations. However, such reforms will never reach a level strict enough to interfere with profitability in specific industries. Nor will state ownership of industries responsible for occupational or

environmental diseases occur to any major degree (135).

Negative selection also applies to the potentialalisation of the health system as a whole. In most capitalist societies, the state generally has opposed structural changes that infringe on private medical practice; private control of most hospitals; and the profitability of the pharmaceutical, medical equipment, insurance, and other industries operating in the health system. While excluding nationalisation through negative selection, the state sponsors incremental reforms that control excesses in each of these spheres, thus maintaining the legitimacy of the whole. As an example of negative selection congressional deliberations in the United States systematically exclude serious consideration of health service (as opposed to national health insurance) that mignt question the appropriateness of private medical practice or the nationalisation of hospitals (152). Another example is governmental regulation of the drug and insurance industries; aside from its erratic effects, state regulation rules out public ownership of these industries.

The state also can use "positive selection mechanisms" that promote and sponsor policies strengthening the private enterprise system and the interests of capital (125, 126). The positive selection of financial reforms like health insurance, for instance, contrasts sharply with the exclusion of organisational reforms that might change the broader political and economic structures of the present system (135).

Medical Ideology

Ideology is an interlocking set of ideas and doctrines that form the distinctive perspective of a social group. Marx introduced a distinction between two levels of social structures. The "infrastructure", or "economic base," comprises the concrete relations of economic production; social class, as determined by ownership or control of the means of production, or both, is the primary feature of the infrastructure On the other hand, the "superstructure" includes governmental and legal institutions. as well as the dominant ideologies of a specific historical period (39). The events of history, in the Marxist perspective emerge mainly from economic forces; this "economic determinancy" gives causal primacy to the sphere of production and class conflict. Thus, the economic infrastructure generally determines features of the superstructure. Ideology and other parts of the superstructure, however, help sustain and reproduce the social relations of production and, especially, patterns of domination (153, 154). Marxist analysis emphasises the subtle "ideologic hegemony" by which institutions of civil society (schools, church, family, and so forth) promulgate ideas and beliefs, that support the established order (129, 155); the "ideologic apparatuses" that the capitalist class uses to pressurise state power (128); and the ideologic features of modern science that legitimate social policy decisions made by "experts" in the interests of the dominant class (156).

Along with other institutions such as the educational system, family, mass media, and organised religion, medicine promulgates an ideology that helps maintain and reproduce class structure and patterns of domination. Medicine's ideologic feature in no way diminish the efforts of individuals who use currently accepted methods in their clinical work and research. Nevertheless, medical ideology, when analysed as part of the broad social superstructure, has major social ramifications beyond medicine itself (157). Recent studies have identified several components of modern medical ideology.

Disturbances of Biological Homeostasis are Equivalent to Breakdowns of Machines

Modern medical science views the human organism mechanistically. The health professional's advanced training permits the recognition of specific causes and treatments for physical disorders. The mechanistic view of the human body deflects attention from multifactorial origin, especially causes of diseases that derive from the environment, work processes, or social stress. It also reinforces a general ideology that attaches positive evaluation to industrial technology under specialised control (5, 135, 158, 159).

Disease is a Problem of the Individual Human Being

The unifactorial model of disease contains reductionist assumptions, because it focusses on the individual rather than the illness-generating conditions of society. More recently, a similar reductionist approach has discovered sources of illness in lifestyle. In both cases, the responsibility for disease and cure rests at the individual rather than the collective level. In this sense medical science offers no basic critical approach of class structure and relations of production, even in the implications for health and illness (135, 159).

Science Permits the Rational Control of Human Beings

The natural sciences have led to a greater control over nature. Similarly, it is often assumed that

modern medicine, by correcting defects of individuals, can enhance their controllability. The quest for a reliable work force has been one motivation for the support of modern medicine by capitalist economic interests (19, 26). Physicians' certification of illness historically has expanded or contracted to meet industry's need for labor (160, 161). Thus, medicine is seen as contributing to the rational governance of society, and managerial principles increasingly are applied to the organization of the health system (113-115).

Many Spheres of Life are Appropriate for Medical Management

This ideologic assumption has led to an expansion of medicine's social control function. Many behaviours that do not adhere to society's norms have become appropriate for management by health professionals. The "medicalisation of deviance" and health workers' role as agents of social control have received critical attention (14, 64, 162-166). The medical management of behavioral difficulties, such as hyperkinesis and aggression, often coincides with attempts to find specific biologic lesions associated with these behaviours (167-171). Historically, medicine's social control function has expanded in periods of intense social protest or rapid social change (172).

Medical Science is Both Esoteric and Excellent

According to this ideologic principle, medical science involves a body of advanced knowledge and standards of excellence in both research and practice. Because scientific knowledge is esoteric, a group of professionals tend to hold elite positions. Lacking this knowledge, ordinary people are dependent on professionals for interpretation of medical data. The health system therefore reproduces patterns of domination by "expert" decision-makers in the workplace, government, and many other areas of social life (173, 174). The ideology of excellence helps justify these patterns, although the quality of much medical research and practice is far from excellent, this contradiction recently has been characterised as "the excellence deception" in medicine (175). Ironically, a similar ideology of excellence has justified the emergence of new class hierarchies based on expertise in some countries, such as the Soviet Union, that have undergone socialist revolutions. Other conutries, such as the People's Republic of China, have tried to overcome these ideologic assumptions and develop a less esoteric "people's medicine" (176).

Studies of medical ideology have focused on public statements by leaders of the profession (in professional journals or the mass media), as well as state and corporate officials whose organisations regulate or sponsor medical activities (177). However, health professionals also express ideologic messages in their face to face interaction with patients (160, 163). The transmission of ideologic messages within doctor-patient interaction currently is the subject of empirical research (178-180)

Comparative International Health Systems

Marxist studies have focussed on three topics in this area: imperialism, the transition to socialism, and contradictions of capitalist reform.

Health Care and Imperialism

Imperialism may be defined as capital's expansion beyond national boundaries, as well as the social, political and economic effects of this expansion. Imperialism has achieved many advantages for economically dominant nations. Marxist critiques have dealt with imperialists of both advanced capitalist countries and socialist superpowers (especially the "social imperialism" of the USSR). (28, 181, 182). Health care has played an important role in several phases of imperialism.

One basic feature of imperialism is the extraction of raw materials and human capital, which move from third world nations to economically dominant countries. Navarro (183) has analysed how the "underdevelopment of health" in the third world follows inevitably from this depletion of natural and human resources, The extraction of wealth limits underdeveloped countries' ability to construct effective health systems. Many Third World countries face a net loss of health wokers who migrate to economically dominant nations after expensive training at home. Workers abroad who are employed by multinational corporations also face high risks of occupational disease (184).

By imperialism, corporations seek a cheap labor force. Workers' efficiency was one important goal of public health programs sponsored abroad, especially in Latin America and Asia, by philanthropies closely tied to expanding industries in the United States (27,27.). Moreover, population-control programs initiated by the United States and other dominant countries have sought a more reliable participation by women in the labor force (185, 186).

One thrust of imperialism is the creation of new markets for products manufactured in dominant nations and sold in the third world. This process, enhancing the accumulatian of capital by multinational corporations, is nowhere clearer than in the

pharmaceutical and medical equipment industries (88,89). The monopolistic character of these industries as well as the stultifying impact that imported technology has exerted on local research and development, has led to the advocacy of nationalised drug and equipment formularies in several countries (187,188)

Imperialism reinforces international class relations, and medicine contributes to this phenomenon (54, 189). As in the U. S., medical professionals in the third world most often come from higher income families. Even when they do not, they frequently view medicine as a route of upward mobility. As a result, medical professionals tend to ally themeselves with the capitalist class, the "national bourgeoisie", of third world countries. They also frequently support cooperative links between the local caplitalist class and business interests in economically dominant countries. The class position of health professionals has led them to resist social change that would threaten current class structure, either nationally or internationally. Similar patterns have emerged in some post-revolutionary socieities. In the USSR, professionals' new class position, based on expertise, has caused them to act as a relatively conservative group in periods of social change (28). Elitist tendencies in the post-revolutionary Cuban profession also have received criticism from Marxist analysts (190,191). Studies of several countries have analysed the relation among class, imperialism, and professional resistance to change (130,131,190-195).

Frequently imperialism has involved direct military conquest; recently health workers have assumed military or paramilitary roles in Indochina and Northern Africa (196-198). Health institutions also have taken part as bases for counter-insurgency and intelligence operations in Latin America and Asia (199).

Health Care and the Transition to Socialism

The number of nations undergoing socialist revolutions has increased dramatically in recent years, particularly in Asia and Africa but also in parts of Latin America, the Caribbean and Southern Europe. Socialism is no panacea. Numerous problems have arisen in all countries that have experienced socialist revolutions. The contradictions that have emerged in most post-revolutionary countries are deeply troubling to Marxists; these contradictions have been the subject of intensive analysis and debate.

On the other hand, socialism can produce major modifications in health-system organisation, nutrition, sanitation, housing and other services. These changes can lead, through a sometimes complex chain of events, to remarkable improvements in health. The morbidity and mortality trends that followed socialist revolutions in such countries as Cuba and China now are well known (190,191. 200-207). The transition to socialism in every case has resulted in reorganisation of the health system, emphasising better distribution of health care facilities and personnel. Local political groups in the commune, neighbourhood, or workplace have assumed responsibility for health education and preventive medicine programs. Class struggle continues throughout the transition to socialism. During Chile's brief period of socialist government, many professionals resisted democratisation of health institutions and supported the capitalist class that previously and subsequently ruled the country (130,131,192-195). Countries such as China and Cuba eliminated the major source of social class: the private ownership of the means of production. However, as mentioned previously, new class relations began to emerge that were based on differential expertise. Health professionals received larger salaries and maintained higher levels of prestige and authority. One focus of the Chinese Cultural Revolution was the struggle against the new class of experts that had gained power in the health system and elsewhere in society (56,202). Other countries, including Cuba, have not confronted these new class relations as explicitly (191).

Improved health care remains linked to the general level of economic development. In some African nations, for instance, severe poverty hampers organisational and programmatic changes. Countries like Tanzania and Mozambique have undertaken health planning that ties general economic development to innovations in health care (208-211).

Contradictions of Capitalist Reform

Although they retain the essential features of their capitalist economic systems, several nations in Europe and North America have instituted major reforms in their health systems. Some reforms have produced beneficial effects that policy makers view as possible models for the United States. Recent Marxist studies, although, acknowledging many improvements, have revealed troublesome contradictions that seem inherent in reforms attempted within capitalist systems. These studies' conclusions are not optimistic about the success of proposed reforms in the United States.

Great Britain's national health service has attracted great interest. Serious problems have

balanced many of the undeniable benefits that the British health service has achieved. Chief among these problems is the professional and corporate dominance that has persisted since the service's inception. Descision-making bodies contain large proportions of professionals, specialists, bankers and corporate executives, many of whom have direct or indirect links with pharmaceutical and medical equipment industries (75, 110).

The private-public contradiction, discussed earlier, has remained a source of conflict in several countries that have established national health services or universal insurance programs. Use of public facilities for private practice has generated criticism focusing on public subsidisation of the private sector. In Britain, for example, this concern (along with more general organisational problems that impeded comprehensive care) was a primary motivation for the recent reorganisation of the national health service (110). In Chile, the attempt to reduce the use of public facilities for private practice led to crippling opposition from the organised medical profession (130, 131, 194). The private-public contradiction will continue to create conflict and limit progress when countries institute national health services while preserving a strong private sector.

The limits of state intervention also have become clearer from the examples of Quebec and Sweden. Both have tried to establish far-reaching programs of health insurance, while preserving private practice and corporate dealings in pharmaceuticals and medical equipment. Recent studies have shown the inevitable constraints of such reforms. Maldistribution of facilities and personnel have persisted, and costs have remained high. The accomplishments of Quebec's and Sweden's reforms cannot pass beyond the state's responsibility for protecting private enterprise (136, 242). This observation leads to skepticism about health reforms in the United States that rely on private market mechanisms and that do not challenge the broader structure within which the health system is situated. (64, 213).

Historical Materialist Epidemiology

Historical materialist epidemiology is a rapidly growing field in Marxist studies of health care. Its antecedents derive from the classic research of Engels (1), Virchow (3, 4) and the nineteenth-century school of social medicine in Europe. Simply defined, historical materialist epidemiology relates patterns of death and disease to the political, economic, and social structures of society (214-216). The field emphasises changing historical patterns of disease and the specific material circumstances under which people live and work. These studies try to transcend the individual level of analysis to find how historical social forces, at least in part, determine health and disease.

Social Class and Economic Cycles

Considerable evidence indicates that the incidence and prevalence of mental illness closely follows periods of economic growth or recession. The relations are complex and differ by social class (217). Recent studies also have linked economic cycles, particularly those that involve expanding or contracting employment, to general mortality and morbidity trends among various social classes and age groups (218, 219).

Stress and Social Organisation

Previous interest in stress usually has focused on the individual life cycle or family unit Historical materialist epidemiology shifts the level of analysis to stressful forms of social organisation connected to capitalist production and industrialisation (220). Hypertension rates, for example, consistently have increased with the disruption of stable social communities and organization of work that is hierarchically controlled and time pressured. These observations apply to countries that have followed capitalist lines of development and socialist countries that have industrialised rapidly (221, 222). Similar investigations of coronary heart disease (223, 224), cancer (225), suicide (226) and anxiety (227) currently are in progress.

Work and Profit

Marxist studies in occupational health emphasise the contradictions between profitability and improved health conditions in capitalist industries (184,228). Specific research has clarified the illness-generating conditions of the work place and profit system with reference to disease entities such as asbestos and mesothelioma (83), complications of vinyl chloride (123). drug abuse (229, 230), and accidents (231). On the other hand, observation of occupational health practices in socialist countries have shown that rapid improvements are possible when private profit is removed as a disincentive to change (176, 232).

Studies in this area focus on the interplay among sex, class structure, and work processes. The varying experiences of women and men are related to their mortality rates and life expectancy (233, 234). Historically, women's use of health facilities and the attitudes of medical practitioners towards women's health problems have depended largely on women's

class positions (161). This conclusion is especially evident from the history of the birth control movement (235), psychiatric diagnosis (236), and gynecologic surgery (237). The unique health hazards and difficulties that women face as housewives (238) and paid workers (239, 240), currently are attracting greater attention.

One unifying theme in the field is modern medicine's limitations (15). Traditional epidemiology has searched for causes of morbidity and mortality that are amenable to medical intervention. Although it acknowledges the importance of traditional techniques, historical materialist epidemiology has found causes of disease and death that derive from broad social structures beyond the reach of health care alone.

Health Praxis

Marxist research conveys another basic message : that research is not enough. " Praxis," as proposed throughout the history of marxist scholarship, is the disciplined uniting of thought and practice, study and action (129). It is important to consider political strategy, especially as it concerns the health system of the United States.

Contradictions of Patching

Health workers concerned about progressive social change face difficult dilemmas in their day-to-day work. Clients' problems often have roots in the social system. Examples abound : drug addicts and alcoholics who prefer numbness to the pain of unemployment and inadequate housing; persons with occupational diseases that require treatment but will worsen upon return to illness-generating work conditions; people with stress-related cardiovascular disease; elderly or disabled people who need periodic medical certification to obtain welfare benefits that are barely adequate; prisoners who develop illness because of prison conditions (64, 241). Health workers usually feel obliged to respond to the expressed needs of these and many similar clients.

In doing so, however, health workers engage in "patching". On the individual level patching usually permits clients to keep functioning in a social system that is often the source of the problem. At the societal level, the cumulative effect of these interchanges is the patching of a social system whose patterns of oppression frequently cause disease and personal unhappines. The medical model that teaches health workers to serve individual patients deflects attention from this difficult and frightening dilemma (64).

The contradictions of patching have no simple resolution. Clearly health workers cannot deny services to clients, even when these services permit clients' continued participation in illness-generating social structures. On the other hand, it is important to draw this connection between social issues and personal troubles (242). Health praxis should link clinical activities to efforts aimed directly at basic socio-political change. Marxist analysis has clarified some fruitful directions of political strategy.

Reformist Versus Non-reformist Reform

When oppressive social conditions exist, reforms to improve them seem reasonable. However, the history of reform in capitalist countries has shown that reforms most often follow social protest, make incremental improvements that do not change overall patterns of oppression, and face cutbacks when protest recedes. Health praxis includes a careful study of reform proposals and the advocacy of reforms that will have progressive impact.

A distinction developed by Gorz (243) clarifies this problem. "Reformist reforms" provide small material improvements while leaving intact current political and economic structures. These reforms may reduce discontent for periods of time, while helping to preserve the system in its present forms : "A reformist reform is one which subordinates objectives to the criteria of rationality and practicability of a given system and policy... (It) rejects those objectives and demands — however deep the need for them — which are incompatible with the preservation of the system." "Nonreformist reforms" achieve true and lasting changes in the present system's structures of power and finance. Rather than obscuring sources of exploitation by small incremental improvements, nonreformist reforms expose and highlight structural inequities. Such reforms ultimately increase frustration and political tension in a society; they do not seek to reduce these sources of political energy. As Gorz (243) puts it: "... although we should not reject intermediary reforms... it is with strict proviso that they are to be regarded as a means and not an end, as dynamic phases in a progressive struggle, not as stopping places." From this viewpoint, health workers can try to discern which current health reform proposals are reformist and which are nonreformist. They also can take active advocacy roles, supporting the latter and opposing the former. Although the distinction is seldom easy, it has received detailed analysis with reference to specific proposals (64, 83, 107, 213, 244).

Reformist reforms would not change the overall structure of the health system in any basic way. For example, national health insurance chiefly would create changes in financing,rat her than in the organisation of health system. This reform may reduce the organisation of the health system. This reform may reduce the financial crises of some patients; it would help assure payment for health professionals and hospitals. On the other hand, national health insurance will do very little to control profit for medical industries or to correct problems of maldistributed health facilities and personnel. Its incremental approach and reliance on private market processes would protect the same economic and professional interests that currently dominate the health system (64,83,213).

Other examples of reformist reforms are health maintenance organisations, prepaid group practice, medical foundations, and professional standards review organisations (64,213). With rare exceptions that are organised as consumer cooperatives, these innovations preserve professional dominance in health care (245). There have been incentives to improve existing patterns of maldistributed services. Moreover, large private corporations have entered this field rapidly, sponsoring profit-making health maintenance organisations and marketing technologic aids for peer review (81).

Until recently, support for a national health service in the United States has been rare. For several years, however, marxist analysts have worked with members of Congress in drafting preliminary proposals for a national health service (152). These proposals, if enacted, would be progressive in several ways. They promise to place stringent limitations on private profit in the health sector. Most large health institutions gradually would come under state ownership. Centralised health planning would combine with policy input from local councils to foster responsiveness and limit professional dominance. Financing by progressive taxation is designed explicitly to benefit low-income patients. Periods of required practice in underserved areas would address the problem of maldistribution. The eventual development of a national drug and medical equipment formularly promises to curtail monopoly capital in the health sector.

Although these proposals face dim political prospects, support is growing. For instance, the Governing Council of the American Public Health Association has passed two resolutions supporting the concept of a national health service that would be community based and financed by progressive taxation (246, 247). This reform contains contradictions that probably would generate frustration and pressure for change. In particular, these proposals would permit the continuation of private practice and, therefore, the inequities of the private-public dichotomy. Yet, because a national health service provides a model for a more responsively organised system, advocacy of this reform seems a key part of health praxis (207).

Health Care and Political Struggle

Fundamental social change, however, comes not from legislation but from direct political action. Currently, coalitions of community residents and health workers are trying to gain control over the governing bodies of health institutions that affect them (111, 117-120). Unionisation activity and minority group organising in health institutions are exerting pressure to modify previous patterns of stratification (248-252).

Gaining control of the state through a revolutionary party remains a central strategic problem for activists struggling for the advent of socalism (124). Party building now is taking place throughout the United States. Advocates of "vanguard party" believe that historically all successful revolutions have resulted from the efforts of a small vanguard who hold consistent ideology and attract mass support during periods of political and economic upheaval. Activists adopting the vanguard approach frequently take jobs as lower-echelon health workers; they recruit members during unionisation efforts and oppose cutbacks in jobs and health services. Supporters of a "mass party" argue that mass organising must precede rather than follow the development of a coherent ideology; therefore, political energies should go toward building alliances that embrace a spectrum of anticapitalist views. Mass party organisers work toward community-worker control over local health programs, occupational health and safety, women's health issues, minority recruitment into medicine, and electoral campaigns for improved health services (254).

Recognising the impact of medical ideology has motivated attempts to demystify current ideologic patterns and develop alternatives. This "counter-hegemonic" work often involves opposition to the social control function of medicine in such areas as drug addiction, genetic screening, contraception and sterilisatian abuse, psychosurgery, and women's health care. A network of alternative health programs has emerged that tries to develop self-care and nonhierarchical, anticapitalist forms of practice; these ventures then would provide models of progressive health work when future political change permits their wider acceptance (255-259).

In anti-imperialist organising, several groups have assisted persecuted health workers and have spoken out against medical complicity in torture (130, 131, 260). Health and science workers also have used historical materialist epidemiology in occupational health projects and unionisation struggles.

A common criticism of the Marxist perspective is that it presents many problems with few solutions. Recent advances in this field, however, have clarified some useful directions of political strategy. This struggle will be a protracted one and will involve action on many fronts. The present holds little room for complaisance or misguided optimism. Our future health system, as well as the social order of which it will be a part, depends largely on the praxis we choose now.

Acknowledgements

The author thanks Betty Boujoukos, Deborah Helvarg, Alexander Leaf, Vicente Navarro, John Stoeckle, Barbara Waterman, and referees of Annals of Internal Medicine for their assistance, criticism, and encouragement.

Grant support : in part by grants from the National Center for Health Services Research (HS-02100) and the Medical Clinics Complex Education Fund of the Massachusetts General Hospital.

HEALTH CARE IN A REVOLUTIONARY FRAMEWORK : Possibilities for an Alternative Praxis

binayak sen and ilina sen

Any health care work is by its very nature, political. It is necessary for revolutionaries to get invovled in the non-reformist reforms to achieve the aim of social revolution. Starting from these premises the authors analyse health care in the revolutionary frame work from their own experiences of health care work in the militant workers' and peasants' movement in Rajhara. They have presented their views as a commentary on and a supplement to Howard Waitzkin's article in this issue.

The note that follows is a commentary on and a supplement to Howard Waitzkin's article on a marxist view of Heath Care. The main theme of this note is the relevance and significance of health care work within a left paradigm in India today.

To begin with however, a general point about politics and health needs to be made. It is common in left political circles to regard health care work as apolitical, or at best, as reformistic. We would argue that politics — the process of exercising power to enhance the material interests of a particular class or social group — permeates all aspects of the super-structure, including health care. The dominant ideology at different times has projected feudal or capitalist models of health care work. It is upto the left movement to expose their ideological foundations and concretely shape a future alternative.

Health Care and Health Status

The words "health care work" have been chosen deliberately, because the distinction between "health" and "health care" has not been fully realised even in debates among groups of politically conscious health professionals. It is generally appreciated in such groups that health care is only one among many determinants of the health of the community, (other important determinants being political economy, education, culture and so on). However, the other side of the coin that health care work and health care systems have a social, cultural, economic and political significance that goes beyond their impact on health status has not been given its due importance. Even when some attempts have been made to come to terms with this aspect of the matter, it has largely been on the basis of trivial notions such as "health as an entry point into the community." This is because the participants in these debates have hardly ever taken the political significance of their work as health professionals seriously. While many of them have sincerely and actively taken up political roles, this has almost always been in areas of work outside the field of health care itself. Both theory and practice have suffered in consequence.

"That health care work and health care system have a social cultural economic and political significance that goes beyond their impacts on health status, has not been given its due importance."

Some Lacunae in Current Approaches to a Theory of Health Care

The realisation that health care and health status are only distantly related has created a feeling of deep frustration among many of those health professionals who are seeking a means, within the health care system, to give expression to their own deep commitment to the people's welfare. Lacking a revolutionary scientific perspective about health care work that would give meaning to their professional practice, tney have taken up one of two types of roles. On the one hand some have retreated into the practice of health care essentially within the bourgeois "welfare" paradigm, seeking to give their work greater relevance by working among rural or urban poor (often at considerable personal cost). In many cases, they have also tried to give their work scientific and technical validity by incorporating positivist notions of a more rational epidemiology, with the intention of creating more efficient models of health care system for the future.

The other group, claiming for themselves a greater familiarity with the revolutionary theoretical apparatus, have nevertheless confined themselves

> *"The entire question of revolution as process of the elaboration of an alternative praxis based on prevailing material conditions and incorporating currently available elements of revolutionary theory has been by-passed."*

almost exclusively within a vulgarised version of the Leninist framework of Party and State policy. Their attention especially in India has largely been focussed on attempting critiques of existing health service systems. This has largely been from the standpoint only of political economy, the general thrust of the argument being something like 'Health problems cannot be solved within the bounds of the capitalist economy.' Some have attempted to devise alternatives, but these have again been based either on existing text book techniques such as epidemiology or on new techniques rooted in capitalist culture such as operations research — these alternatives wait for their realisation on a dens ex machina, characterised variously as "political will" (D. Banerji) or "dictatorship of the proletariat."

In both these cases, the entire question of revolution as **process** — of the elaboration of an alternative praxis, based on prevailing material conditions and incorporating currently available elements of revolutionary theory — has been by-passed. This is not to negate the importance of capturing State power, but to emphasise that the process of delegitimising the existing ideology in all walks of life has to begin here and now.

Waitzkin's Paper : Critical Comments

The importance of Waitzkin's article is that it serves as an overview — ableit a very brief one — of the area of interaction between the practice of health care and current concepts in Marxist revolutionary theory.

It remains to comment upon some of the points that he has raised in his article.

a) Reformist Versus Non-Reformist Reform

With the execption, perhaps, of academic and technical research, all the kinds of work available for the revolutionary practice of health care require participation in piecemeal reform programmes. The distinction between reformist and non-reformist (or revolutionary) reform, outlined by Gorz and quoted in Waitzkin's article, is therefore deserving of careful study and reflection. However, the **necessity** of such reforms to any revolutionary programme has not been given adequate importance in Waitzkin's article. He contents himself by saying in the opening sentence of this section, that "when oppressive social conditions exist reforms to improve them seem reasonable."

The necessity of social reform programmes was put forward much more strongly by Roza Luxemburg in her attack on Bernsteinian reformism, "Reform or Revolution", she starts at the very outset, "Can the social democracy (i. e. Communists) be against reforms ? Can we counterpose the social revolution, the transformation of the existing social order, our final goal, to social reforms ? Certainly not. The daily struggle for reforms, for the amelioration of the workers within the existing social order, and for democratic social institutions, offers to the social democracy the only means of engaging in the proletarian class war and working in the direction of the final goal — the conquest of political power and the suppression of wage labour. Between social reforms and revolution there exists for the social democracy an indissoluble tie. The struggle for reforms is its means; the social revolution, its aim."

The distinctions mentioned by Gorz apply mainly at the level of health policy rather than the practice of health care. Moreover, Waitzkin seems to sound as though there are or can possibly be, a set of independent criteria on the basis of which it is possible to decide whether a proposed reform is reformist or non-reformist. The fundamental question of the basic political framework within which the struggle for these reforms is to be carried out, is not emphasised.

How are the differences between reformist and non-reformist health care praxis to be established ?

For the last three years, in Rajhara, the Chhathisgarh Mukti Morcha has been running a health programme based on a militant organised workers' and pesants' movement. Some indications may

> *"Between social reforms and revolution there exists for the social democracy an indissoluble tie. The struggle for reforms is its means, the social revolution, its aim."*

perhaps be obtained from the experiences gained in the course of this work.

The first difference, is that reformism is directed primarily at suppressing emerging class antagonisms and contradictions between state power and peoples' power. Revolutionary reform, on the other hand, by the very fact that it is based on a militant recognition of class antagonisms and of the oppressive nature of state power, is directed towards precisely the opposite goal. Consequently, the most important goal of a revolutionary reform programme is not the achievement of the reform towards which it is putatively directed, but to further the political struggle of which it forms a part.

The second difference is that revolutionary reform does not derive its strength from any exogenous group of "reformers' standing outside the mainstream of the popular consciousness. Instead, its primary reasources are the political consciousness, organised strength and creative power of the working class and peasantry. Consequently, we cannot take a single step in such a programme without considering the direction in which the people want it to proceed. Any attempt to work out new ideas has to be preceded by an effort to explain these to the people, and to establish them in the popular consciousness.

"The Revolutionary reform does not derive its strength from any exogenous group of «reformers» standing outside the mainstream of the popular consciousness."

This also means that at any given moment, the direction of the programme cannot be governed by a "a priori" consideration of the appropriateness of the measures taken. The existing direction is always limited by the existing perception of the people, of the issues around which the programme is formed, based on their collective past experience. Nevertheless, it is necessary for those leading such programmes to have a deep and concrete historical understanding of similar programmes, and of the issues as they exist in the community. (In the case of health care, this would mean that we should possess a knowledge of epidemiology and a knowledge of the health service programmes.) This knowledge is necessary so that it may be posed in a constant dynamic tension to existing perceptions, so that the two may come close to each other in a series of successive approximations.

The third difference is that revolutionary reform is vitally conscious of the inevitability of its own failure. That is, we believe that the ills which owe their existence to an oppressive social order cannot, except marginally, be cured except by a radical restructuring of that order - that is - revolution Consequently, we do not hope nor expect that our praxis will succeed in effecting more than marginal improvements in the health of the people or even in the availability of curative care. However, our attempt is to direct the energies of the people into the establishment of an institution and a programme which reflects their aspirations. This presents to the people a radically new vision of an alternative social order, and a living critique of the existing one.

b) Medical Care and Ideology : Hegmony and Counter Hegemony.

Waitzkin refers in the first paragraph of the section on Medical Ideology to the thought of Gramsci. However, once again the reference is so brief that anyone not already familiar with the Gramscian idea of Hegemony would be unable to make much of the reference. It is worth going into the idea in slightly greater detail, since it forms one of the chief plants on which a revolutionary medical praxis is based.

Gramsci considered that the ruling classes exercised and perpetuated their control over the whole of society not only through the exercise of political force, but also through the power of the ideology elaborated by the ruling class intellectuals. Through this process of legitimisation the ruling class obtained the consent of the whole of society to exercise the power of Government on its behalf.

"In order to establish its own hegemony the working class must do more than struggle for its own narrow sectarian interests, it must be able to present itself as the guarantor of the interests of society as a whole. .". Gramsci had a broader view of the party than Lenin perhaps partly because he had greater experience of a developed bourgeois society. He conceived of it as deeply committed to an ideological and cultural struggle as well as to the seizure of state power. . . Thus he advocated a party that was an educational institution offering a counter-culture whose aim was to gain an ascendancy in most aspects of the superstructure (as opposed to directly political institutions) before the attempt was made on state power. The party organisers trained the workers in the assumption of control over their own

lives and thus anticipated a post-revolutionary situation. (David Melellan : Gramsci, in "Marxism after Marx").

Ideology in Health Care

Through its medical institutions — ranging all the way from state run hospitals through the Jasloks and the mission hospitals to the lovliest private practitioner, the ruling class is constantly engaged in the elaboration and perpetuation of an ideology that serves to oppress and control the workers and the poor.

There are three specific elements of ideology in health care which are not adequately dealt with by Waitzkin and hence need special consideration.

a) The Concept Of Charity :

The first, and in our view, the most important of these, is the concept of charity, or "daya". This is not considered in Waitzkin's article. Perhaps this is because he writes from a Western background, in which there already exists a clear distinction between the humanist and technical aspects of medical practice.

However, in India, we are all familiar with the idea that the medical practitioner, be he ever so crass, attains spiritual merit with each transaction in which he plays the role of healer. The objective caste status and the subjective Brahminical manner of most practitioners of modern medicine further reinforce this tendency. The influence of this tendency is yet again reinforced and consciously generalised by the religions symbolism that pervades the atmosphere and even the architecture in many of the important centres of modern clinical excellence. (Apart from admittedly religious hospitals—Christian, Hindu, Muslim or Jain — good examples are commercial-community based hospitals like Jaslok in Bombay and the Calcutta Hospital in Calcutta).

Of course, the function of the healer neither can nor should be totally divested of transcendent elements of spiritual and psychological authority. Neither can the role of the patient ever be totally divested of its elements of spiritual and psychological dependency.

However, where the healing institution has been built up on the initiative and with the resourcee of a militant organised working class movement, and functions specifically within a revolutionary framework, and with healers who live among the people and aspire to be identified as revolutionaries rather than as do-gooders, this relationship of authority and dependence can have a counter hegemonic influence and thus reinforce working class militancy and self confidence.

(b) Ideology and Technology :

The second area of ideology in health care that needs to be considered is that relating to medical technology. Waitzkin's article does go into this aspect briefly, in the section entitled "Medical Science is both esoteric and excellent." A much more penetrating and thorough going critique of the disabling and iatrogenic nature of modern medical technology is contained in the work of Illich- to which, surprisingly, this section makes no reference. Illich's work also contains the notion of a demystified, locally-controlled, human-scale technology. His notion of a society incorporating these ideas is free of class, free of history and independent of political process. He makes a fetish of Technology.

This is not the place to embark on a critique of Illich. However, irrespective of the viability of the solutions proposed by him, the notion of demystification of technology is important to any alternative praxis in the field of health care. This is because an important part of the ability of the existing health care system to reproduce ruling class ideology is due to its basis in an esoteric, monopolistic technology, seemingly divorced from its roots in ordinary mannual and human skills. It is this technological basis that creates within the field of medical practice a steadily widening gap between mental and manual work.

"An important part of the ability of the existing health care system to reproduce ruling class ideology is due to its basis in an esoteric, monopolistic technology, seemingly divorced from its roots in ordinary manual and human skills."

It is to reverse this trend that the concept of the voluntary health worker is important.

In the health programme at Rajhara, a training programme for voluntary health workers has been put into operation. However, these workers are not seen primarily as agents who, by performing simple

tasks in a decentralised fashion, increase the efficiency of the health programme. Rather, the VHWs are seen as ordinary workers, who, by undertaking to perform certain healing functions on the basis of their skills in and understanding of modern medical technology, render the entire range of medical technology accessable to ordinary human understanding. The training programme also repeatedly emphasises the idea that the primary duty of the VHWs is to spread their understanding of health care technology among their comrades.

C) Internal Organisation

A third ideological function that a health care programme can perform is to create, within the internal organisation of the programme, an image of what the social dynamics of such a programme in a socialist society might be. In particular, the undemocratic and hierarchical functioning of most health care institutions is something that any alternative praxis of health care must try to change.

Conclusion

In conclusion, the limits of this note — all too apparent to the authors must be emphasised strongly. In the first place, it is a comment on Waitzkin's article, and must be read against the background of the article i. e. not independently.

Secondly, throughout this note, in order to achieve the limited aims which the note seeks to fulfil, an attempt has been made to emphasise.

a) health care as against health status.

b) Superstructural elements as against more fundamental aspects related to political economy.

c) the revolutionary possibilities of an alternative praxis of health care as against the humanist values embodied (or at least imminent in) more traditional form of health care work.

It would be disastrous if on the basis of this note, anyone should conclude that we consider the second halves of these contrasts to be unimportant. On the contrary, in each case, it is only possible to emphasise the former where the latter is already taken for granted. This selective emphasis must be kept in mind throughout the reading of this note.

Finally, except where direct quotations have been made, no references are included. The points made in this note have emerged through discussions and practice engaged in with many groups of friends and colleagues over a long period of time.

Orwell's Hints to Writers

George Orwell in his 'Politics and the English language' attacks jargons severely and says: "Modern writing at its worst does not consist in picking out words for the sake of their meaning and inventing images in order to make the meaning clearer. It consists in gumming together long strips of words which have already been set in order by someone else, and making the results presentable by sheer humbug..... They will construct your sentences for you, even think your thoughts for you, to a certain extent and at need they will perfrom important service of partially concealing your meaning even from yourself." He has given some rules for writers to follow: (i) Never use a metaphor, simile or other figure of speech which you are used to seeing in print (ii) Never use a long word where a short one will do (iii) If it is possible to cut a word out, always cut it out (iv) Never use the passive when you can use the active. (v) Never use a foreign phase, a scientific word or a jargon word if you can think of an everyday English equivalent (vi) Break any of these rules sooner than say anything outright babarous..... The most important thing to remember is that good writing is not a collection of beautiful phrases or idioms. Good writing is the result of clear thinking.

(Excerpted from *The Hindu* May 8, 1984)

POLITICAL ECONOMY OF HEALTH CARE IN INDIA

An Outline

amar jesani and padma prakash

Medicine is not a socially independent activity. It is always articulated within a specific mode of production. Therefore, the dominant medical practice in India is bourgeois medicine and health care helps to strengthen and expand the capitalist mode of production. It also reproduces the capitalist relations of production at every level of its operation. The development of health care in India is examined in the context of the dynamics of socio-economic changes which have taken place since independence.

"My inquiry led me to the conclusion that neither legal relations nor political forms could be comprehended whether by themselves or on the basis of so-called general development of the human mind, but that on the contrary they originate in the material conditions of life, the totality of which Hegel, following the example of English and French thinkers of the eighteenth century, embraces within the term 'civil society', that the anatomy of this civil society, however has to be sought in political economy."

Karl Marx
Preface to
A Contribution to the Critique of Political Economy.

Every human being, in the last analysis, after removing all covers of social existence, is natural and therefore, biological. The flesh, blood and bones comprising the human body are too materialistic for anyone to deny their existence. But this natural living individual is not a lone, isolated entity. Through centuries of social development, the individual has evolved socially, coming into interaction with nature and while transforming it, has himself/herself been transformed. In the course of this social development, human beings have entered into various types of relationships in order to produce the necessary means of subsistence and to reproduce his/her own species and so given rise to the complex organisation of, to use Hegel's term, the 'civil society.'

The 'natural' or the biological forms the fundamental basis on which, historically, the social existence of human beings has developed. In the course of this development completely new forms of objectivity have arisen and although such objectivity have no analogy in nature, they still remain socially transformed natural objectivities.

To illustrate, in primitive societies, the exchange of necessary goods was not the rule but, more the exception. Here the natural use of those goods, to satisfy hunger or other needs was the predominant consideration. But with the evolution of a more complex social organisation leading to the evolution of a social system based on commodity production such goods which were necessary and useful for life also acquired, exchange value of their own. Every commodity in the capitalist economy has therefore, two characters, the use value and the exchange value. But this exchange value cannot be located or identified in the commodity. Exchange value is then, an exclusive social category which has no analogy in nature. "The main tendency of the developmental process that arises in this way is the constant increase both quantitative and qualitative of purely or predominantly social components, the 'retreat of the natural boundary' as Marx puts it. "(Lukacs, 1978).

Health and medicine are such social categories which have reference not simply to the biological existence of the human being, but to the social nature of such existence. That is why the understanding of health has changed according to the needs of different social systems and the needs of the ruling elite of that social system..

Features of the Marxist Approach to the Critique of Political Economy of Health

Four major features of the Marxist approach to the political economy of health may be identified—

The Social Production of Illness : Medical definitions of health and illness are located in the clinical pathology of the individual. In its narrowest and most limited form this definition locates the cause of disease entirely in the human body and disease is seen as a consequence of an unwanted attack of biological entities, bacteria, or virus, on the human body. The control of disease is seen to mean the control or eradication of these bacterial or causative agents. The concept that ill health is

directly related to the socio-economic formation and to the production relations in society has been put forward by several analysts since Engels wrote the *'The Conditions of the working class in England'*. Turshen traces the origins of what is termed the 'clinical paradigm' and discusses its weakness. According to her the discipline that comes closest to explaining the notion of collectivities is medical ecology. "Medical Ecology, thus asserts a relationship between environment, disease and man but selects only biological and socio-cultural factors as relevant." (Turshen 1977). This too ignores the illness generating forces in society. Doyal and Pennell in their book *Political Economy of Health* have elaborated on the evolution of the clinical paradigm in modern medicine. They discuss the direct and intimate relationship between the process of commodity production and destruction of health and between economic underdevelopment and health. (Doyal & Pennel, 1981). This view does not exclude or deny the operation of the biological mechanism which cause illness. The concept that ill health can only be understood as a consequence of the dynamics of class contradictions in society, and that the occurrence of disease is intimately related to the social formation within which the biological, physical and chemical operate is one of the major marxist contributions to the critique of political economy of health.

"Health and medicine are social categories which have reference not simply to the biological existence of the human being, but to the social nature of such existence."

Health as labour power: Under capitalism health is defined as an integral component of an individual's labour power or productive capacity. Labour power being a commodity under capitalism has a specific exchange value — the quantity of social labour necessary to reproduce it.... just as any other commodity does. In other words, the exchange value of labour power is the value of consumer goods and other services necessary to keep the worker and his/her children fit enough to work at a given intensity of effort. But to maintain this level of effort, or the maximum level of productivity, a certain level of physical and mental health is vitally necessary. Below that level of health the capacity to work falls off, and with it, the amount of surplus value that will be generated. The capitalist is simply not interested in the level of health beyond this, even though the worker will be vitally interested from the point of view of the quality of life and not of productive capacity (Schatzkin, 1978).

From this point of view of health as labour power, Schatzkin argues that medical care services are designed for maintaining the requisite level of health, a kind of labour power 'repair and maintenance service'. While educational services help to maintain the knowledge and skill component of work capacity, medical services help to maintain the physical and psychological components. Since the provision of health is part of maintaining labour power, it represents to the capitalist, a part of the wages he must pay out, directly as wages or indirectly as 'social' wages in the form of medical services.

The commodification of health care: A commodity is an external object which through its qualities satisfies human needs of whatever kind and is produced for exchange in the market. Health care is one such commodity. Historically, throughout most of human history, health care was an organic part of a communal society. It has often been indistinguishable from religious or social activities, none of which were exchanged (although gifts were often presented to traditional healers). As communal societies were conquered by feudal and eventually capitalist societies, health care was taken out of the hands of traditional healers and placed in the domain of doctors and midwives, who engaged in health care for a price i.e. as part of a money exchange. The physician was an independent producer selling the product of his or her own labour (Roder and Stevenson, p. 19-108).

But "capitalist production is not merely the production of commodities, it is by its very essence, the production of surplus labour" (Marx *Capital*, p. 644). The capitalist can organise the production of surplus value through the provision of health care and can realise high profits in this service industry. It is immaterial whether the surplus value is realised directly through the productive activities in the clinics and hospitals owned by the capitalist or indirectly, through the provision of health care by the state to maintain or increase the productive capacity of labour.

Medicine as a social relation: Vicente Navarro has concretised our understanding of how medicine should be viewed within the perspective of the social system. He argues that medicine or health

services is a social relation and reproduces the dominant relations of production. Medicine, therefore, has been different under different modes of production. He argues that since the mode of production is reproduced not only at the economic but also at the political and ideological levels, medicine contributes to the reproduction of the mode of production at the economic, political and the ideological levels and that medicine is always articulated within a specific mode of production.

These are the features of Marxist approach or methodology which we will use to examine the political economy of health care in India. But any attempt to examine the development of health care in India in the context of socio-economic development brings into focus the subject of the mode of production in Indian agriculture. We are aware that this subject has generated a lot of debate amongst Marxists in the last decade and there are divergent viewpoints. We will not here review the entire debate that has taken place nor put forward our viewpoint on the subject and substantiate it. Our focus is the political economy of health care. We will, therefore, endeavour to show that, the very efforts of the Indian State to penetrate the remotest corners of the agrarian set-up through the provision of health care facilities; is not any isolated and non-social phenomenon. But the efforts in fact strengthen and reproduce the already existing and expanding capitalist relations of production (whether in "pure" forms or intertwined with the pre-capitalist forms).

At the same time, we must admit that this analysis is our first attempt and the vastness of the exercise has made us very aware of the inadequacies in the sphere of information and data. The most evidently thin area of the outline is the lack of analysis and attention to the social roots of ill-health and disease in India. By and large, we have merely assumed that the patterns of illness are reflective of the class, caste and sexual contradictions and are influenced by the level of development, both quantitative and qualitative, of the social system. We have also assumed that changes in the patterns of illness are directly related to changes in socio-economic system, and have proceeded to focus on the changes in health care in light of the change in the mode of production. Our objective is to locate the crisis in health care and medicine within the larger political perspective for class struggle.

Health care under British imperialism

Western medicine came to India in the 17th century. The first medical men to set foot on the sub-continent were the surgeons sailing with the merchant ships of the maritime nations of the time. Throughout the century a number of Europeans found employment as surgeons and physicians in the Courts of the kings and nawabs. By the end of the 18th Century all the factories of the East Indian Company had at least one surgeon in their employ and the Indian Medical Service had been founded (Crawford, 1914).

At that point of time the medicine practised by the company doctor was hardly different from local systems. The doctor of the day had a limited range of therapeutics and curative procedures . . . . herbal medicines, a very few disease-specific chemical preparations, the new 'exotic' drug the Peruvian cortex (cinchona) for intermittent fevers, blood letting, venesection and other such procedures which had been in vogue since the time of Galen. The birth of modern scientific medicine was yet to be. In the following century however, there were enormous developments in the content, theory and practice of medicine in Europe. Not only had the knowledge base of medicine expanded but it was being structured to meet the needs of the dominant class. For instance, the two major disease casuality theories that were competing for acceptance, the contagion theory and an environment theory were more than **medical** theories and their incorporation into contemporary medical thought was dependent on how they affected the operations of the dominant class of the time. During the first half of the 19th century the contagion theory which suggested quarantine measurs as a means of controlling disease, was the best accepted. But with the increased movement of goods and of people towards the middle of the 19th

"Since the mode of production is reproduced not only at the economic but also at the political and ideological levels, medicine contributes to the reproduction of the mode of production at the economic political and ideological levels and that medicine is always articulated within a specific mode of production."

century, quarantine measures proved ruinous to the new entrepreneurs and merchants. One important reason for the acceptance of the miasma theory which located the cause of disease in unsanitary conditions was the potentially disastrous effects the acceptance of the contagion hypothesis would have caused (Tesh, 1982).

By the end of the 19th century, the sanitary reform movement in Britain had resulted in limited state intervention in the form of legislations and in the creation of institutions for administering them. But these refoms were actually self-limiting. Although they affected a section of the capitalists whose profits came from housing, water supply and sewerage dealerships, they served the needs of capital by decreasing the cost of disease. At the same time public health work and preventive medicine could never gain the status nor weild the same influence as clinical medicine. Public health work highlighted the shortcoming of capitalism and it would mainly benefit a class which was incapable of conferring status. (Turshen, 1977). On the other hand, clinical medicine with its focus on the individual rather than the social conditions underlying disease states offered a means of diverting public attention from the ills of capitalism.

"One of the aims of the planning was to aid the capital accumulation in the private sector."

The origins of the sanitary reforms in India are rooted in a different set of circumstances. After 1857, and the take over by the Crown, the number of troops on Indian soil increased and the health of the army became a subject of discussion. Moreover, cholera which had been confined to India so far broke out in a devastating epidemic in Europe. The British colonial government was pressurised into initiating sanitary measures in the Presidency areas. But these measures did not give rise to a public health system and the government chose instead, to encourage the setting up of medical research facilities for the assault on tropical diseases, an assault master minded in England. (Ramasubban, 1982).

Outside the government framework, a number of missionary groups and individuals had also begun to set up hospitals and medical institutions. For instance, a number of maternity hospitals and training centres were set up to teach midwives the 'modern' methods of childbirth. The funding for these came from wealthy Indians who wished to set up hospitals as memorials. (Billington, 1973).

Medical Colleges were set up to train assistants and a large number of Indians were taking avantage of the opportunity. The upper castes were specially encouraged to enter these colleges. Right from the beginning allopathic medicine in India acquired an upper caste elite base. (Banerji, 1974). Women too were given special concessions, so that the new maternity homes could be well-staffed.

The development of 'scientific' clinical medicine which embodied bourgeois ideology and relations of production was far more important than the creation of a public health system which might expose the true nature of British imperialism.

The health care network under the British comprised desultorily implemented sanitary measures and a fair number of hospitals and dispensaries with a growing number of medical research facilities undertaking work on tropical diseases under the tutelage of European doctors and researchers.

The path of development consciously adopted by the Indian ruling classes at the time of Independence.

The increasing popularity of modern allopathic medicine amongst the Indian elite strata was not an accidental phenomenon. It was rather a part of the process of emergence of Indian bourgeoisie as an economically powerful and politically shrewd class under British imperialism. As we will show later in this section, the choice of modern allopathic ("scientific") medicine as a basis of development of health-care system in India was deliberate (despite the fact that other choices and concrete proposals existed), and was in consonance with the path of socio-economic development adopted by the Indian ruling classes. To substantiate this statement, we will examine the situation at the time of independence under three headings : a) the strength of Indian bourgeoisie at the time of independence, b) the political and economic strategy adopted by the Indian bourgeoisie for strengthening its class rule, and c) the health care strategy adopted as a part of development perspective.

(a) The strength of the Indian bourgeoisie at the time of independence : On the eve of independence, although, India's total economy was overwhelmingly agricultural, substantial industrialisation had taken place. In fact, India was much

better placed than most other colonial or semi-colonial countries of that time.

India's domestic capital, at the time of independence nearly occupied an equal place with foreign capital in Indian economy.(Bettelheim, 1968). According to the same source, foreign capital's sphere of influence was particularly in the principal foregin currency earning industries (tea, jute and cotton) and in those which were the main sources of power in India (petroleum, coal, electricity).

In assessing the political strength of the Indian bourgeoisie at the time of independence, two points should be understood. Firstly, Indian capital had to develop under the tight control of British imperialism. In its confrontation with foreign capital and imperial policies, it was but natural that a tendency developed towards developing stronger economic and political organisations of its own. Moreover, Indian Capital did not develop through "free competition." Due to several intrinsic factors specific to India, and due to the fact that World Capital was already at the monopolistic stage, there was naturally a tendency for Indian industral capital to take monopolistic forms. This situation helped it to organise its various groups with much more ease and also made it more shrewd and alert in extending right political patronage.

Secondly, the Indian bourgeoisie was politically shrewd enough to understand the importance of Gandhi's ideology of harmony between capital and labour. During the 1918 textile workers' strike in Ahmedabad the newly formed Bombay Mill-owners' Association utilised this opportunity to establish contacts with Gandhi. Subsequently in 1921, with the launching of the Swadeshi movements they found in Gandhi a representative leader and in the Congress their representative Party. It is important to note that from this point onwards, the bourgeoisie never lost its political leadership of the nationalist movement. Thus, at the time of independence, the party of the Indian bourgeoisie, the Indian National Congress maintained its leadership of the nationalist movement and very meticulously implemented the strategy of the Indian bourgeoisie for the post independence growth of capitalism in India.

b) The political and economic strategy adopted by the Indian bourgeoisie for strengthening its class rule: The Indian independence was not a social revolution in which, one class through violent means seizes political and socio-economic power from another. In fact, independence was just transfer of political power from British imperialism into the hands of Indian bourgeoisie, keeping the socio-economic structure of the society more-or-less intact. Moreover, under the Mountbatten plan this transfer was affected through negotiation and bargain. Therefore, after taking over the reins of State power, the Indian bourgeoisie did not adopt radical measures attempting to do away with India's pre-capitalist forces. In so far as those forces did not seriously obstruct its plan of gradual transformation of Indian agriculture through state intervention it adopted a policy of compromise and accommodation.

At the same time, in the turbulent 1940s the Indian bourgeoisie feared the militancy of the working masses. It should be noted that from the later half of 1930s, the mass unrest had attained serious proportion. On the industrial front, the number of strikes in 1937 reached 379, the highest since 1921. Between 1942 and 45, the cost of living went up by 200 percent. The year 1940 saw another strike wave, in which workers of cotton textile, jute, oil, coal, iron, and steel and many other industries participated. The number of trade unions went up from

---

"The Indian bourgeoisie opted for a model of health care service in which health care could be transformed into a commodity."

---

188 in 1938 to 515 in 1944 with the membership rising from 3,65,450 to 5,09,084 (Dutt, 1983).

At the same time, the All India Kisan Sabha, which took a leading role in fighting against government repression and had helped organise self-help movements for food and funds, quadrupled its membership between 1942 and '45. (Dutt, 1983, p. 279). The end of the war saw two significant peasant movements - the Tebhaga movement between '46 and '47 in what is now Bangladesh and the Telangana struggle in '46 and '51 in Andhra. These were the most outstanding indicators of peasant ferment brewing all over the country.

The political ferment also spread to the armed forces in '46. The RIN mutiny and the support it gained in Bombay from the working class and middle classes shook the Indian bourgeoisie. Thus although, the Indian left, because of many reasons into which we cannot go in in this article, could not destabilise the bourgeoisie nor have a perspective

to take control of the national movement, the latter was forced to recognise the explosive potential for militancy among the labouring masses. The realisation that the mass pressure the bourgeoisie had so far used to their advantage could get out of hand, forced them into granting concessions in the overall plan of development at independence.

In the context of the above, the bourgeois strategy that developed after independence was twofold. Parliamentary democracy was accepted because it would widen the mass base of the regime, to give room to the contending socio-economic forces in the governmental block and to provide a safety valve for mass discontent. This method of bourgeois rule granted universal franchise, formal political democracy, equality before the law and so on all at one stroke. In the Constitution, it gave the State Power a clear bourgeois impress by making the right to private property a fundamental right. The right to work, the right to receive free health care, education and so on were not included in the list of fundamental rights but were relegated to being directive principles. Also, for the future socio-economic development of India, planning with the active intervention of the State in the economy was adopted as the best way for industrial development and for the transformation of backward agriculture.

"The expansion of capitalism is dependent on a politically stable and healthy labour force"

Briefly, the aims of planning with the active State intervention in the economy were the following: (i) To develop an infrastructure of the heavy industry, transport, communication, and energy, so vitally necessary to overcome the most glaring weaknesses of industry or the under-developed capital intensive industries. This development required huge investment and a long gestational period for invested capital, the private sector was not yet ready for this. (ii) To aid the process of capital accumulation in the private sector. This was to be done providing private capital with easy access to the infrastructure, by employing private contractors in the operation of public sector, by enriching individuals or groups of individual bureaucrats and so on, and (iii) To carry out limited agrarian reforms, to provide facilities for agricultural development and strengthen and expand existing bourgeoise forces leading ultimately to the modernisation of agriculture on a capitalistic basis.

c) The health care strategy adopted as a part of the development perspective : At the time of independence, three major reports concerning the health system in the new nation saw the light of the day. In 1939 the national planning committee had set up a subcommittee to prepare a plan for health. In 1940, the Chopra Committee was constituted at the first health minister's conference. And the Bhore committee began work in 1943, and was charged with the task of conducting a survey of the entire field of public health and medical relief on which to base plans for post-war development in the health field. (Bhore, 1946). It advocated a doctor-centered system of health care and urged the creation of a vast health infrastructure. Its main inspiration were the Flexner report (which consolidated the establishment of 'scientific' medicine in the US) and the Goodenough Committee (which had been a more recent report restructuring medical education in U.K.). Briefly, the Bhore committee recommended (i) the main focus of all health measures should be to enable people to enjoy life to the fullest extent and to help the individual reach his maximum level of productive capacity; (ii) the future health care system should be a doctor-based, hospital-centered system with a proliferation of health institutions; (iii) a salaried service should be preferred over private practice although "any apprehension that private practitioner will be seriously affected to their detriment by our proposals for a state health service is unfounded." (Bhore, 1949 p. 16); (iv) occupational and industrial health was an important aspect of health services; (v) maternal and child health was to be given a high priority; and (vi) consequent on the development of a health infrastructure, the pharmaceuticals and the surgical goods industries would have to be encouraged to expand.

The Chopra committee (the committee on Indigenous System of Medicine) report was published in 1948 and made recommendations which, had they been implemented at that time, would have resulted in a drastically different system of medicine. It saw an urgent necessity for evolving one unified system. It pointed out that the Bhore Committee had been rather silent on the question of indigenous systems in their grand plan for the development of health services in India. The Chopra Committee, in fact, had drawn up a plan for health services where the primary levels would mostly use indigenous system and the taluk hospital and beyond would practise 'synthesised' medicine. Almost all the recommendations were rejected. It

was decided that a full course in modern scientific medicine was to be the basis on which other systems were to be engrafted.

The Indian bourgeoisie opted for a model of health care service in which health care could be transformed into a commodity. Even in adopting the recommendations of the Bhore committee, it selectively incorporated those recommendations which contributed to the growth of the health infrastructure and the consolidation of bourgeoisie and its concomitant organisation. The development and consolidation of allopathic 'scientific' medicine was also a deliberate choice which offered several advantages which we will elaborate in a later section. For the moment, it is sufficient to state the supposed resolve of the Indian bourgeoisie to develop indigenous systems did not get translated into any meaningful programmes and India was well set on the way to enlarging the world base for the practice of 'scientific medicine'.

First fifteen years of Planning

(a) Growth of industries hastening captial accumulation : The public expenditure on development in the first three five years plan period was as shown in Appendix 1.

From the second plan, Industry and mining started receiving the attention of the planners and in the third plan it got the first priority. The major investment in this branch was in heavy industry. By 1965, substantial changes took place in the industrial structure. The gross value of output of light industry increased from Rs. 17,100 million in 1951 to 35,900 miliion in 1965, i. e. it more than doubled in 15 years. In this period, the output value increased by 8.5 times in the heavy industry. The share of heavy industry in the total output of manufacturing industries went up from 22 to 52 percent. The investment in heavy industry went up from 43.4 percent of the total investments in the manufacturing industries in 1951 to 79.8 percent in 1965. (Shirokov, 1980).

Thus, at the end of third plan period, the public sector had set up productive plants mainly in the sphere of heavy industry. It could do this by receiving soft-term loans from the Soviet and other 'Socialist' countries.

Even while developing the industrial infrastructure, in this period a slow but steady transformation of the Indian agrarian sector, was also begun.

(b) The Transformation of Indian agriculture The progress in the agricultural sector in the first fifteen years can at best be termed modest. The production of food grains recorded a much smaller growth than that of cash/industrial crops. The rise in grain production did not outstrip or even equal the rise in population. The sectoral allocations in the first plan gave first priority to agriculture, community development and irrigation which together accounted for 35.8 percent of the outlay. After that, the percentage share of the outlay in these areas consistently decreased.

Throughout this period agrarian legislation strengthened the position of the rural upper classes. The richer peasantry were able to gain greater freedom from their landlords and were able to increase their holdings. The big landlords were being transformed into capitalist farmers. The conditions of the poorer peasantary considerably worsened during these years. On the whole there was a slow development of rural capitalism. (Betteleheim, 1968).

Agrarian reforms were in this period directed not so much at transforming the modes of production in agriculture, as adapting the colonial agrarian structure to fit the pattern of growth envisaged by

---

"The programmes like malaria control must be seen as death control programmes preceding the birth control programmes of a later period."

---

the bourgeoisie. They were directed at eliminating the intermediaries and middle men and reducing the effect of feudal and semi-feudal relations. Agricultural policies and programmes favoured those landlords who had undertaken cultivation on their own, rather than rentier landlords (Joshi, 1969). The non-implementation or failure of those portions or land reforms or the 'failure of land reforms' was not surprising, considering as Davey remarks aptly, that the state assemblies were dominated by landlords and kulaks. Likewise, land ceiling legislation was easily circumvented. The Failure to ensure security of tenure has resulted in evictions. In the Punjab alone, the number of tenancies fell from 583,400 in 1955 to 80,520 in 1960 (Davy, 1975).

The Community Development Programme, launched with US aid in the first plan further strengthened the economically and politically dominant classes. Later evaluations showed that 70 percent of the benefits from agricultural extension went to

the elite groups, the more affluent and influential agriculturists'' (Dubey, 1969). The CD projects worked through existing village institutions which were more often than not, dominated by landowning groups. The 'Shramdan' drive which was supposed to encourage people's participation, in terms of free labour on road construction and repair, was usually contributed by the poor who had nothing to gain from roads; while those who benefitted from the roads, the large landholders who needed to transport goods out, got away by merely supervising. The CD programmes not only strengthened the rural elite but also created bureacratic institutions which acted as a link between the rural elite and the government.

After 1960, agrarian policies and programmes became openly favourable to rich peasants. The Ford Foundation sponsored Intensive Areas Development Programmes with its packages of credit, modern inputs, marketing facilities and technical advice was one such. This meant also the increasing use of high yielding varieties and fertilisers. Between 1960 and 1966 the consumption of fertilisers more than doubled (Davey, 1975). The two disastrous droughts in '65 and '67 upset bourgeois plans of strengthening and developing rural captitalism.

"Bourgeois radicalism either in the form of reports or legislations or programmes can best be viewed as concessions gained by working class militancy."

(c) Health Care in a Planned economy: The evaluation of health services and the growth of medicine in India can only be analysed in the background of the development strategies employed by the Indian bourgeoisie. As we have seen the primary aim of Indian capitalism at independence was the consolidation and expansion of capitalist relations and the transformation and integration of pre-capitalist mode of production. Accordingly, the health strategies that were chosen directly or indirectly supported and strengthened the drive for capital accumulation.

There were four factors, one may call them constraints, which limited the bourgeoisie's options in the health sector. Firstly, they functioned in an economy linked to and subservient to World capitalism. Secondly, they were committed to planned development. Thirdly, they had to function within the garb of a 'welfare State' and fourthly, in the beginning at least, they had to counterpoise and diffuse working class demands and tensions. What were the health plans and programmes of the period and how did they advance bourgeois aims and ideology?

In 1951, the population of India was 361 million. Nearly 38% of the working population were wage-earners (Bettelheim, 1968). The economic growth envisaged required a healthy and productive labour. However, the recent series of famines and droughts, increased exploitation of war, further deterioration of the abysmal public health and sanitary services, the post partition exodus had resulted in a labour which obviously could not contribute its best in terms of productivity. The situation also favoured political instability. The expansion of capitalism is dependent on a politically stable and healthy labour force and these called for measures to reduce mortality and morbidity in the Country. Moreover, the unhampered bourgeois hegemony of the national movement had been paid for by making promises to the working class and its leaders as well as the progressive educated elite. In response to the growing mass discontent the bourgeoisie had to make visible gestures which could demonstrate their concern and their intention of fulfilling promises. The creation of large health institutions, and building of medical colleges and research establishments was a most appropriate strategy.

At the same time it was recognised that the reinforcing of capitalist ideology and reproduction of bourgeois class relations was necessary to the growth and development of capitalism. 'Scientific' medicine which had evolved and matured under capitalism was obviously the most appropriate choice. In this sense, the adoption of modern medicine as the dominant system of medicine and the creation of hospital infrastructures where it could be practised was an ideological as well as political necessity.

1) Reduction in Morbidity and Mortality: At the time of independence 50 percent of all deaths were estimated to be from epidemic diseases. The expectation of life at birth was 32.45 years for males and 31.66 for females (Health Statistics, 1982). Cholera, Malaria, tuberculosis and smallpox were major killers. In 1950 malaria killed 75 million and

it was estimated that 156 million work days were lost causing a loss of Rs. 75 million. PAC Report-1983-84). Moreover, "aggregation of labour in irrigation, hydroelectric and industrial projects is attended with severe outbreaks of malaria". (First F. Y. Plan, 1952, p. 500-501). Tuberculsois was the other major killer which claimed fives lakhs lives annually and rendered 25 lakh people ill. It was estimated that 900 to 1000 million mandays were lost because of the disease. (First F. Y. plan 1952).

The Malaria control programme co-ordinated all Malaria control activities and consisted of DDT spraying, treatment with antimalarial drugs and providing malaria engineering services wherever there were developmental irrigation and hydroelectric projects.

The Tuberculosis Control Programme included vaccination with BCG, clinics and domiciliary services, and aftercare. The emphasis was on prevention with BCG. Both these programmes depended on international agencies like the UNICEF and WHO for supplies of necessary chemicals and vaccines.

Both these programmes, especially Malaria Control Programme, achieved spectacular results in the beginning, after which their success levelled off. By 1956 the mortality due to malaria had declined to 19.3 million and in the first year of the programme the number of workdays saved was estimated to be 116 million.

These programmes, especially the malaria programme conducted like a military campaign were conceived in such a manner that they were bound to fail. Cleaver (1976) points out that programmes like malaria control must be seen as death control programmes preceding the birth control programmes of a later period. Together they constitute "the means for obtaining control over populatian growth and thus over the supply of labour". These have been the strategies sought by business whenever they have sought to invest — in US, South, SW Asia or China.

These programmes have also been used to divert attention from the real causes of ill-health by equating disease eradication to 'technical' measures such as DDT spraying in the case of malaria or BCG vaccination in the case of TB. Both eradication and immunisation programmes constitute the 'medicalisation' of socially and economically determined problems of health. By introducing disease control and later eradication programmes, the Indian bourgeoisie was ensuring control over labour supply. Its early spectacular results also aided the legitimation of the 'welfare state'.

By the '60s increasing urbanisation with a 40 percent increase of urban population, inadequate housing and living conditions, low availability of food and impoverishment and unemployment had pushed up disease incidence rates. The health impact of new industrial processes that were being introduced went unrecorded. In industry, intensification of labour coupled with chronic malnutrition accounted for a rise in industrial injuries which rose by 30 percent between 1961 and 1966 while work force rose only by 16 percent (Ajit Roy, 1973)

2) Institution Building : Both the Bhore committee and the First Plan took serious and anxious note of the lack of medical facilities. Low health status was seen as being primarily because of lack of medical facilities. The major emphasis in the first fifteen years was an increase of hospitals, beds and dispensaries and the numbers of doctors, nurses and other health personnel. (Appendix 2).

"The faithful implementation of recommendations is contradictory to the interests of capital and can be brought about only by continued struggle."

The first plan envisaged an increase of 24 percent in the number of hospitals, a similar increase in the number of urban dispensaries, a 11 percent increase in the number of rural dispensaries and a 10 percent increase in hospital beds. The number of maternity and child health centres both in urban and rural areas was also to be increased. More than fifty percent of the budget for medical schemes was allocated to the establishment of hospitals and dispensaries.

Public health expenditure went into the provision of water supply and health sanitation, the major share going to Madras and Bombay. Since training of personnel of all kinds was so important, institutions and facilities for training were given high priority. The establishment of the All Indian Institute for standardising and co-ordinating post-graduate medical education was also initiated (First

F. Y. Plan). This venture, as well as others, such as the setting up of the Virus Research Centre in Pune, and the expansion of the All Indian Institute of Hygiene and Public Health was assisted by the Rockfeller Foundation. This trend for increasing the medical infrastructure continued throughout the fifties and the early sixties.

The Mudliar committee which published its report in 1961, recommended a strengthening of the district hospitals as against any expansion of primary health centres. In its opinion, the resources in regard to personnel, finance were not available sufficiently for any further expansion of PHCs.

It must be pointed out that most of the expansion in facilities took place in urban areas and a majority of the medical graduates set up practice in cities. Together with this, the pharmaceutical industry which had made small beginnings after the first world war had expanded a little during second world war. By the beginning of the '50s, India was self-sufficient in all the galenical preparations, most of the vaccines and alkaloids. But medicines like Pencillin, Streptomycin and sulphas were largely imported. After 1956, many foreign subsidiaries which had begun as trading operations went into the production of formulations, and public enterprises such as Hindustan Antibiotics and Hindustan Organic Chemicals were started in the late '50s mainly with the help of Soviet aid and technical know-how. But the major expansion of production was of the foreign subsidiaries. By '68-'69 the average profits for pharmaceuticals was 20.3 percent (Rangarao, 1977.)

"The rationale of the Indian bourgeoisie in adopting massive family planning drive was a means of controlling labour."

In short, the health care system being developed was a doctor oriented, hospital centered, curative system largely dependent on modern pharmaceutics with its locus in urban areas. For the Indian bourgeoisie, such a health system created a large base for consumer durables which were manufactured in the private sector. It also motivated the growth of the pharmaceutical and chemical industry. Increase in the number of hospitals and medical institutions also meant many more 'converts' to both 'scientific' medicine and the growing array of drugs and associated products. Also, these institutions were an emphatic and 'visible' assertion of the State's concern in fulfilling its 'Welfare' goals and in keeping with the 'leap frogging' approach to catch up with developed countries that was being advocated.

This is not to deny that the increase in the numbers of health personnel and institutions was not necessary or useful. That would be patently untrue. But arguments which place blame for the current crisis on the non-implementation of 'radical' recommendations of the Bhore committee are inadequate. Given the path of development chosen by the bourgeoisie, the alternative offered in, say the Bhore report or the Community Development Programme could never have been implemented. Bourgeois radicalism either in the form of reports or legislations or programmes can best be viewed as concessions gained by working class militancy. The faithful implementation of recommendations is contradictory to the interests of capital and can be brought about only by continued struggle.

3) Reproduction of bourgeois social relations and social control : The bourgeoisie always adopts policies and strategies which will reproduce and reinforce bourgeois social relations.

(i) The adoption of allopathic medicine as the dominant medical system : From the outset, it was clear that the western allopathic system was to be the medicine of choice. In the period between 1948 and 1960 four committees Chopra, Pandit, Dave and Udupa) were constituted to plan for the development of indigenous systems of medicine in the country. By and large the only recommendations which were implemented were those which helped to suppress or discourage the growth of indigenous systems. We have already noted what happened to the Chopra Committee report. Later reports increasingly emphasised the need to examine indigenous medicine 'scientifically'. Further, it was generally agreed that the only area where indigenous medicine could play a role in the health system was in area of drugs and remedies.

Why was the adoption of allopathic system as the dominant system of medicine so important to the bourgeoisie? Firstly, the class and sex biased, positivist individualist ideology of modern medicine reflected bourgeois ideology. The hospital system reproduces the social structures of bourgeois society and by doing so reinforces and authenticates it. Modern medicine with its dependence on mysterious sounding drugs and its array of task specific

functionaries and unfamiliar language facilitated the monopolisation of knowledge and skills. From this comes the power and influence to those who have access to this knowledge viz; the doctor and to a lesser extent other health professionals. These professionals, mainly doctors, who shared the same class background as the bourgeoisie were necessary for the legitimation, strengthening and maintenance of the capitalist order. In recognising and locating 'scientific' medicine as the dominant system, the bourgeoisie were also acknowledging and encouraging the role of the educated elite.

(ii) The development of maternal and child health services : Concern for the health of women, as mothers, has a long history in India. At the time of independence, the sex ratio (women to 1000 women) had already started declining. But none of the health plans nor policy statements were ever concerned with this. However, investment in the health of the child (and incidentally its mother) were seen as an investment "for building a sound and healthy nation" (First F. Y. Plan). These facilities were seen as facilities through which women could fulfil their socially determined primary role as mothers. In consequence, women's health needs became subordinate to the needs of the family. The deterioration of women's health and women's status through the '60s is to a large extent the result of the policies and programmes that have been adopted by the Indian bourgeoisie.

The provision of MCH service,however relevant, in the absence of primary care accessible to women indirectly perpetuates 'the myth of motherood' and the social location of women under capitalism mainly as 'reproducers of labour.'

(iii) Health Education. One of the most important component of 'preventive' services was and has been health education, which mainly reinforces the victim-blaming ideology of modern medicine. It also helps to mask the social roots of illness and disease. The emphasis on changing life styles rather than on changing the socio-political environment which endanger such lifestyles protects the existing power structures in society and the exploitative mechanisms of capitalism.

Changes in Health Policy after 1965

In the health sector the trends which were discernible in the first decade after independence continued to be prominent until about the '70s. In this section,[we will analyse the seemingly drastic change in health policy and programmes in the mid '70s in the context of socio-political and economic developments.

The two consecutive droughts in the mid-sixties had brought impoverishment and ruin to the rural landless and agricultural labourers. The proportion of rural population below poverty line reached a new hight of 57.9 percent (Shah). The nett per capita daily availability of food-grains was around 402 grams the lowest since 1952. It was in this situation that the Green revolution was launched. The concept itself, according to Davey was a part of America's post war strategies and was an extension of the agricultural research of the Rockfeller and Ford Foundations. The Green revolution also coincided with the glut in the world fertilizer market.

In the arease where the green revolution took root the crop yields shot up and also altered the agrarian structure. There was an increase in the numbers of agricultural labourers and despite mechanisation, the demand for labour also went up. In time the landless labour gained in strengh and emerged as a distinct class (Bhalla, 1983). Most of these also belonged to the deprived sections — the scheduled castes and scheduled tribes. At the same time the introduction of new technology and easier credit facilities had strengthened the small and marginal farmers and increased their staying power. Rich farmers were unable to buy them out. However there were no basic contradictions between the large and marginal/small farmers. These holdings constituted two-thirds of the cultivating households. In such a situation agrarian struggle was inevitable. Agitations for better wages were also, in reality struggles against caste oppression.

In areas outside the green revolution area, such as M.P., Rajasthan, Gujarat, parts of Bihar and

---

"Reduction of state inputs in health care and a great involvement of the private sector were the outstanding features of the national health policy and is in keeping with the objectives of the new bourgeois strategy for health care."

Orissa and West Bengal, it was the small and middle farmers who gained most by the introduction of new technology. They soon began to challenge the economic and political power of the landlords, most of whom were absentee landlords. The interests of these new rich small and marginal farmers were contradictory to both that of the landless as well as that of the politically influential landlord. Having gained economically this section of the peasantry, the middle farmers who were usually from the middle castes, began to develop political clout both on the regional and the national scene. They also began to demand development inputs which would enable them to gain a qualitatively better standard of living... electrification, consumer goods and health services.

By the beginning of the '70s, industrial production had stagnated, the rise in national income being only 4 percent in 1971-72. The population went on rising, hence the labour force had continued to expand. The total work force was 184 million, 8 percent or 15 million were unemployed. While wages had remained stagnant the average product per worker had increased. So, the employing class had benefitted, thus polarising income (Davey- 1975).

The Fourth Plan's emphasis was on rural and agrarian programmes and the enormous emphasis on family planning. This was an attempt to postpone and forestall the crisis and also a recognition of the new and growing political influence of the middle peasantry. In the health sector almost half of the allocation went to family planning.

There have been a number of analyses of why there was an emphasis on family planning. The most obvious explanation is of course, the enormous spurt in numbers in the previous decade, which was mainly because of decrease in death rates. Even-though epidemic diseases had not been eliminated there was a decrease in the number of death in each of these epidemics. Another less obvious reason was that given the high rates of unemployment and impoverishment, the sheer numbers presented a threat to the stability of the system. That there was imperialist pressure, through the use of conditional international loans and such, cannot of course be denied. But the rationale of the Indian bourgeoisie in adopting a massive family planning drive was a means of controlling labour supply to suit the expansion of more capital intensive modern industries.

Throughout the first half of the '70s there was a marked increase in the number of industrial conflicts, strikes, peasant agitations, tribal movements, student and mass movements most of which were directly or indirectly concerned with economic grievances. The Gujrat and the JP movement were against price rise initially but later made political demands. The Naxalite movement and the revolt of the tribals in Srikakulam, were more broad based and directly challenged class oppression. That brutal repressive measure were used to break and suppress them was an indication of the insecurity of the Indian bourgeoisie. The world economic situation had also changed by the mid '70s. Many advanced capitalist countries were on the brink of a third technological revolution. The national bourgeoisie realised that if they were to forge a new relationship with the world capitalist economy they had to re-structure the industrial sector by reducing state intervention and increasing opportunities for foreign investment. This also meant disciplining and controlling labour and stabilising the political climate.

Inputs into rural development therefore served two purposes — firstly, they facilitated the further penetration of capital and secondly, 'visible' efforts such as provision of health care, educational facilities, electricity, low capital intensive 'appropriate' technologies would not only nullify the growing discontent and political influence of the new rich 'middle' peasants and capitalist farmers but also strengthen them as a class who would associate with the industrial bourgeoisie in opposing and suppressing working class struggles. Moreover, these efforts would also mean an expanded market for the new technological consumer products.

The Fifth Plans' Minimum Needs Programme is just one such strategy. In the health sectors it was being realised that a hospital based health system supported by vertical programmes such as Malaria Eradication and Family Planning no longer performed either this ideological role or achieved their socio-politcal objectives. There had not been any large scale improvements in health indicators in the past years. Their role as advertisements for the bourgeoisie's concern for 'welfare' had long outlived its usefulness. Moreover, it was no longer a good economic option. The amount spent for welfare of the working class comes out of the surplus value being created. If this no longer achieves the purpose of either maintaining and reproducing labour or of strengthening class relations by reproducing and legitimating the capitalist order, the loss in surplus value cannot be justified. The only answer was a change in strategy. 'Scientific' medicine gave way to a 'community'

conscious science-based medicine which was accommodating enough to allow the operation of other systems under its hegemony.

Through the '70s a number of voluntary agencies funded by industrial houses, Christian missions or foreign development agencies, and individual professionals frustrated and disgruntled with the existing system began to 'experiment' with alternative health strategies following essentially the 'health-by-the people' approach. The rising cost of health care, of medicines and equipment provided a further impetus to many. Naturally enough this approach had an instant appeal to a mass of socially-conscious urban and rural youth, plagued by the threat of unemployment and sensitive to the increasing deprivation of the masses. Many of these projects achieved initial success in improving health indicators such as infant mortality or maternal deaths, epidemic deaths and achieving high immunisation rates.

In 1975, the Srivastava Committee was the first official document which put forward a proposal for health care which created a new health functionary.. the community health worker. Based on the premises that most of the commonest health problems are of the easily preventable kind and may be easily looked after at the village level, the committee proposed the training of selected villagers as the first contact in the new rural health care structure. It suggested a well organised and graded structure of dispensaries, hospitals and referal services.

The alacrity and the speed with which these proposals were accepted and implemented by the government is a measure of how appropriate and urgent they were to those in power. By then, in 1977 the Janata Party, a configuration albeit temporary, of the commercial bourgeoisie and capitalist farmers had dislodged the Congress, which then represented mostly the industrial bourgeoisie. The Janata Party saw the provision of rural health care as a means of fulfilling election promises. Moreover, they were the representatives of just those sections who would be benefitted most... the rural rich and middle peasantry. Democratic selection processes notwithstanding, the community health workers were certainly not to come from among the poor.

Around this time several countries, met under UN auspices at Alma Ata and signed the Declaration which proposed just such a strategy. The international move conferred on the programme a high status which would play a part in persuading reluctant and antagonistic professional bodies to co-operate.

In 1980, the new strategy for rural health was formalised and integrated into overall bourgeois strategy in the form of a national health plan, proposed by the ICMR-ICSSR committee. This report, a good indicator of the bourgeois radicalism, in the '80s, proposed a pyramid model of health care, based on a diffused primary health care programme relying on limited, cheap, labour-intensive techniques and technology and a smaller, capital-intensive, mainly curative, referral and specialist service using sophisticated, modern, high tech resources, and the hospital system. Both the terminology and the spirit of the report was greatly influenced by Illich. It saw the organising of primary health care on a community basis as an essentially 'political experience' which would enable people to fight other battles and this in turn would set in motion a 'process to strengthen a decentralised, democratic and participatory social order'. (HFA, 1981). The major recommendations of the HFA were incorporated into the Sixth Plan.

In 1982, the government of India published a Statement on National Health Policy. It enunciated an integrated, comprehensive approach toward the future development of medical education, research and health services. Broadly it followed and repeated the recommendations of the HFA. But in doing it re-emphasised certain trends which had been barely discernible in the HFA and the Sixth Plan. For instance, it focussed greater attention on reducing governmental expenditure and utilising untapped resources to encourage the establishment by private practice professionals . . . . and financial and technical support to voluntary agencies (NHP 1982-). More importantly, it focussed on the need to establish a referral system which could provide speciality and super speciality services. Again, to reduce governmental expenditure private investment in such fields was to be encouraged. In providing water supply and sanitation too, appropriate technologies were to be used 'to reduce expenditures'. The 'involvement of community' in the implementation was also seen as a means of reducing costs. Thus, reduction state of inputs in health care and a great involvement of the private sector are the outstanding features of the national health policy and are in keeping with objectives of the new bourgeois strategy for health care.

We will examine briefly how the alternative strategy fits into the overall strategies adopted by the bourgeoisie since last quarter of 1970.

(1) The growing mass of rural poor has little access to any kind of health care. Diseases which could be easily prevented were still claiming lives. Maternal and infant mortality rates were still pretty high. Community health workers, however inefficient orinappropriately selected would ameliorate sickness conditions to some extent. The credit for this in turn, would accrue to the party in power.

(2) More importantly the new alternative is demystifying medicine just sufficiently for people to learn to use and to become dependent on modern drugs. If until now injections had a 'magic' value, soon metronidazole or B-Complex which the CHVs use will become familiar enough for people to ask for and demand them. This expands the base of operation for pharmaceutical companies.

(3) As we have noted earlier, the medicine practised by the community health worker was no different from the medicine practised by a hospital-located health functionary. Its content was the same but its garb was different. Therefore, the dominant/dominated relations that it embodied are strengthened and reproduced. Since the outreach of these rural health alternatives is so much larger, bourgeois ideology is being strengthened. It is possible that these programmes are hastening the degeneration of indigenous practices and local healers.

As the main disseminators of health education messages, the village health workers are also spreading the ideology of 'victim blaming' shifting attention from socio-political roots of illness and masking class contradictions. In locating the main focus of health care in the family, programmes determine and lend support to the oppressive institutions which are so necessary to the maintenance of capitalist order.

Moreover, the village health workers have generally been from among the rich and middle peasants and middle castes. The acquisition of new techniques and knowledge has led to a different level of monopolisation strengthening the power base of this class. The existing selection process does not cut across existing power relations in society, including that of man and woman, and so reinforces them.

(4) This separation of primary and referrel facilitated the modernisation and development of productive forces of modern medicine on the one hand, while at the same time appearing to cater to the needs of the masses. The new strategy attempted to resolve the growing contradictions between the relations of production and production forces in modern medicine. The introduction of CAT scans, linear accelerators, laproscopy and so on in the last few years must be viewed in this context. The new 'medical leasing' companies which have started to function will facilitate the introduction of new technology and instruments in health institutions.

Conclusion

Medicine is not a socially independent activity. The evolution of medicine and the development of health care can only be understood within the larger perspective of the overall development of the Indian economy and the changes in the relation of production that came about.

The choice of 'scientific' medicine and a hospital-centred structure through which it can be practised was a deliberate choice on the part of the Indian bourgeoisie and was a necessary component in achieving the objective of a capitalistic transformation of India. This also had a profound impact on the traditional practices in India not simply in terms of making their techniques less effective, but more so by changing the social relationship that such practices of those techinques embodied. Such transformation has further strengthened the domination of bourgeois medicine.

The community health approach so lauded since the late '70s initially gave an illusion that radical changes were being brought about in health care. We have argued here that this approach was never intended to bring about any radical changes but on the contrary, it was very much a part of a strategy to expand the hosptial-centred health care structure at the primary and secondary level in the rural areas. Not only. The strategy also involves inviting private investment and collaboration in the health care system with state gradually reducing its inputs in health. The community health approach also helps the pharmaceutical and surgical goods industry (which is largely in the domain of the private sector) to expand their domestic market.

Lastly India with her vast area and dense population divided into class, caste, sex, cultural, ethnic and a host of other differences is probably the most complex of socio-economic formations rendering attempts to properly comprehend it a most difficult task for the social scientists. There is always the danger of making sweeping generalisations and over-simplifications in providing an analytical outline of the development of health care in the context of the dynamics of socio-economic changes in India. We have not taken into consideration in

this analysis the regional differences and the unevenness of socio-economic development. But we have identified the dominant trend of development at the general level and analysed how the development of health care services is integrated with it. We are also aware that we have not included in our analysis the relative strength and political influence of medical organisations like the Medical Council of India nor their relationship with the pharmaceutical and surgical goods industry.

Given the vastness of the subject it was only natural that all aspects could not be covered. But the article, we hope, will generate enough interest in this subject so that the analysis can be deepened and broadened.

A CULTURAL CRITIQUE OF MODERN MEDICINE

anant phadke

The Cultural Crisis of Modern Medicine, John Ehrenreich (Edited), Monthly Review Press, New York and London, 1978, 300 pages, $7.50

It is quite often alleged that marxism is interested only in the economic aspects of society or a part of it. But this view is at best a misunderstanding. Marxism does attach primary importance to the analysis of the process of social production ("economic aspect") of any society but it is also quite concerned with a concrete analysis of the superstructural aspects. In the field of analysis of Health (determinants and dynamics of health status of the people) and Medicine (as science and technology and as system of professionals geared to intervention based on this science and technology) marxists have given due primary importance to the political economy of health. But the ideological/cultural aspects of health and medicine have also been analysed by Marxists. *The Cultural Crisis of Modern Medicine* is one of the most important contributions in this field. What follows is more of an introduction to this book than a critical review.

The book is a collection of a dozen essays abridged, and edited by John Ehrenreich. In his lengthy introduction, John Ehrenreich first traces the historical and political origins of the "cultural critique" of modern medicine. Ehrenreich alleges that the political, economic critique concentrates its fire on the inequitable distribution of health-services, on the problems of organisation of medical-care, and is not much concerned with the nature of medicine itself. Ehrenreich is not entirely correct in his assertion. There are marxist analysts who analyse the political economy of health not primarily from the standpoint of distribution of medical services. For example, *The Political Economy of Health* by Lesly Doyal and Imogeh Pennel is primarily concerned with showing the relationship between phases in the bourgeois economic development in Britain with the development of Medicine and it shows the ideological/political role of medicine at different historical junctures in England. It is however true that traditional marxist analysts have almost exclusively focussed on the lack of proper medical facilities to the poor and on medicine as a money making industry.

Ehrenreich points out that the question of the purpose and nature of medicine was brought forward by the women's movement, and movements of minorities who pointed out that in their experience, medicine was not so much a helpful measure as a tool of ideological, and cultural domination. Along with the radical community movements, the other sources of cultural critique were some critical health analysts (Dubos, Mckeown, Powls, Illich) who showed that modern medicine has not at all been as effective and beneficial as it is made out to be. Most of the infectious diseases in Europe were well on the way out before the era of antibiotics. When antibiotics came, the West had by then acquired the so-called diseases of industrialisation, cardio-vascular diseases, accidents, cancer, psychological and geriatric problems, and so on for which medicine has not much to offer in real terms.

Ehrenreich in his introduction also points out the problems of a cultural critique. For example when one says that the existing system of Medicine is not very effective, or helpful, this gives a ground for conservatives and reactionaries to argue for a reduction in the subsidised, social medical-care-programmes. In backward, developing societies, even a rise in the availability of conventional medicine can help to improve the health status of the population. In such countries a cultural critique is not a priority, though it is still relevant in such situations. In such situations what is needed is more medical care and also a better one, a helpful one and not as a tool of domination. He points out other problems such as dependency, professionalism, problems of technology. Capitalism has given a particular shape to these problems. We should reject their capitalist form but the problems in Ehrenreich's view do not end there and hence concrete socialist alternatives need to be worked out.

Medicine and Social Control : The Book is divided into three parts. The first Section consists of three essays which deal with how modern bourgeois medicine acts as one of the mechanisms of **Social Control**, of perpetuating and consolidating bourgeois social norms and ideology. *Medicine and social control* by Barbara and John Ehrenreich makes a critique of Talcot Parson's (the famous bourgeois sociologist) concept of 'sick-role' which governs the understanding of the relations between the sick-person and

the society in bourgeois society. The medical profession decides as to who is sick and how a sick person should behave. A particular person may be pronounced as below normal, or neurotic even if he/she is just different from or rebelling against what the doctor and the bourgeois ideology regards as normal. A worker may be ill, but the doctor may declare him to be normal and fit for work so that the employer does not have to give any concessions to the worker during his illness. Like law or religion, these medical verdicts cannot be challenged. This power of the medical profession is one of the mechanisms through which people are made to behave in the way in which bourgeois society wants them to behave. The authors show that the medical social control could be either disciplinary or cooptive. Disciplinary control mainly directed against the poor, discourages people from saying that they are sick by making sickness an unpleasant, painful episode--- long waits at the doctor's clinic, unpleasant reception by the medical profession, costly, painful treatment and so on. Cooptive control, on the other hand coopts the recipient of medical care (mostly well-to-do, rich people) into the dominant mainstream of social-cultural life by creating, and reinforcing a certain stereotyped understanding of what constitutes proper social behaviour. There has been a tremendous increase in the jurisdiction of the medical profession (from brith to marriage to old age), in the availability of medical services, and through these two, in the dependency of the people on the medical profession. The authors show how the situation of interaction between the highly trained, higher-middle-class doctor and a patient from a poorer or a minority community or a woman is a fertile situation for conveying ideological messages and cultural values; and how this is done in the U. S. today. This framework is a good starting point for us here in India to explore our own situation here.

Irving Kenneth Zola in *Medicine as an Institution of Social Control* continues with the same theme and further unravels the ramifications of this mechanism. Her analysis however, focuses exclusively on the domination of the medical profession without linking it with the capitalist character of today's medicine and today's society. It reads more like a radical attack on modern medicine as such, and not on its capitalist character. Nowhere does Zola make a distinction between the capitalist limitations of modern medicine and the potentialities created by it which can be used in a socialist society.

Marc Renaud in *Structural constraints to state intervention in Health* first shows how the medical profession, even after the advent of modern medicine, has played a very small role in the improvement in the health of the people. He quotes important authorities to back-up his statements. He then shows how, by their very nature, the incidence and effects of the so-called diseases of industrialisation (for example, cardio-vascular diseases) are not amenable to curative services. So long as the profit-seeking giant corporations continue to decide what we eat, what work we do and how we live and travel, which consumer goods we shall use, ill health is going to continue. The state allows this basic mechanism of production of illness on a social scale unaffected. It also allows the commodification of medical-care. All it does is rationalise the access to medical care and make it less costly. But the drug-industry and the health-industry in general, would continue to live happily. The manufacturers of ill health would then continue to accumulate profits as before. The bourgeois state is not prepared to stop the production of surplus-value even if it threatens the health status of the people; it cannot stop the commodity character of medical care. This is the limit of state intervention in bourgeois society. Renauds analysis is a good concrete case study of the limitations of state intervention in bourgeois society and a solid indictment of the limitations of medical care in this society.

Women, Illness and Medicine : The second section of the book consists of five concrete case-studies which demonstrate how medicine in bourgeois society acts as one of the mechanisms of social control over women. In *Sick women of the upper classes* Barbara Ehrenreich and Deirde English show how medicine in 19th century Britain reinforced stereotyped images of women that they are inherntly prone to illness, and that they ought to be frail, and engaged only in "feminine pursuits" like decoration, courtship, motherhood. If a woman were to engage herself in social, intellectual activity, she would be regarded as being abnormal and inviting illness. By "women" the medical profession meant only upper-class women since it had a vested interest in the cult of female invalidism among its upper-class clients. Medicine gave a " scientific basis" to the male-chauvinistic ideas by proposing "scientific" theories which had no real scientific basis. Scientific knowledge of how sexual, and reproductive organs function did not exist then. This opened a wide door for the male prejudices amongst medical men to be propagated as scientific opinions. medical treatment was more of a punishment. It is quite a shock to read about the barbaric methods of treatment empolyed by doctors

to treat women including the application of leeches, blister-producing counter-irritants to genitalia, removal of the ovaries (for "conditions" like troublesome menses, eating like a ploughman, erotic tendencies, dysmenorrhoea...!) and others. The account of hysteria by the author is also extremely revealing. This short essay is one of the most damning indictment of medicine in the 19th century.

It is quite a surprise to learn that doctors were opposed to the birth-control movement as late as the 1920s. Linda Gordon in her piece on *The politics of birth-control* documents this opposition and the reasons for it. She also shows the connection between the left, the feminist and the birth-control movement, and how later, due to the problems created by World War I, the birth-control movement lost the leftist political edge. Later, the medical profession instead of oppossing birth control, decided to co-opt and monopolise it. With their entry and with the decline of the role of the left, the birth-control movement no more remained a people's movement. Along with the feminist birth-control movement, there was the tendency in the U.S. of new eugenics. The essential argument of this eugenics was that unfit people such as criminals, and paupers, were genetically inferior. They were therefore, interested in the compulsory birth-control for these "enemies of civilisation." Because of the lack of strong anti-racist traditions in the U.S., even the feminist used the eugenics arguments for the propagation of the birth-control movement. This, together with the lack of interest of the leadership in "reformist. peripheral" issues like birth-control, resulted in the decline of the paople's birth-control movement and made it into one dominated by conservatives, reactionaries, racists and the ilk. In the 1930's however, eugenics fell into disrepute because Hitler's Nazi Germany took it over. This zigzag movement of the status of birth control makes very interesting reading.

The next three articles show how the ideology of sexist or of scienticist, commercial professionalism affects clinical practice even today. Doris Haire in her *Culturul warping of child birth* makes a point by point critique of the various technical measures employed by American obstetricians for conducting deliveries from confining the normal woman to bed, to shaving the birth area, to Routine Electronic Foetal Monitoring. She argues that all these interventions are not really indicated and that they are not beneficial to patients but to doctors and to commercial interests. It is because of these unnecessary and potentially hazardous medical interventions that the U. S. is outranked by 14 other nations in the low rate of infant mortality although the U. S. is the most prosperous and advanced nation in the world. The U. S. leads all other developed countries in the rate of infant deaths due to birth injury and respiratory distress such as postnatal asphyxia and atelectasis. The reason ? - monopolisation by doctors of midwifery (unlike in Europe) and their overintervention-list strategy. One cannot disagree with Doris Haire. One may add that even in countries like Britain with a long history of legal, expert, trained midwifery, doctors more or less decide the strategy of intervention and the midwives have to follow it. The midwives are fighting this out and are putting forward a series of arguments, facts, figures, and alternative practices. This disease of monopolisation and overintervention is no longer unique to the U. S.

The other two essays in this section focus on the sexist biases in the medical textbooks. Mary Howell exposes the paediatricians whereas Dianna Scully and Pauline Bart pin down the gynaecologists for their sexist bias and their ignorance about female sexuality. Like other articles in this book, these are also made up of quite concrete stuff.

The third section of this book deals with **Medicine and imperialism**. Frantz Fanon in his *Medicine and Colonialism* depicts the hatred, distrust, and alienation felt by the Algerian people towards their colonial masters and their doctors. Most of the doctors owned land or some business and were directly a part of the exploiting system, even of political oppression and torture. This explains the ill-feeling of the Algerian people about these doctors. As opposed to this, the Algerian people were extremely cooperative, helpful to the health programmes and to the doctors of the National Army of Liberation. It is difficult to fully appreciate the situation in a colonial country for those of us from the younger generation who have never experienced it. But Fanon has made his point clearly.

E. Richard Brown in his *Public Health in Imperialism* shows how the Western interest in tropical diseases and public health in tropical countries was motivated by their imperialist interests. The American imperialists wanted an overall penetration into South America for higher profits. But the productivity of these people was low. The reason for their "laziness" was found to be diseases like hook-wom. Hence the Rockfeller Foundation's first act after its inception in 1913 was to create an International Health Commission to extend worldwide the hook-worm and public health programmes initiated in the U.S. The programme against hookworn in Costa Rica

succeeded and resulted in a 50 percent rise in labour productivity. The Rockfeller Foundation had quite clearly expressed why it put a priority on the hookworm programme. "On account of the direct physical and economic benefits resulting from the eradication of the disease and also on account of the usefulness of this work as a means of creating and promoting influences." This latter element was as important as the first one. Brown convincingly shows how. Brown clearly welcomes the betterment of the health status of the population but shows that the chief aim of these programmes was to prepare better conditions for the accumulation of imperialist capital, and people's health was subservient to this aim. He shows that Health was defined as the capacity to work and other aspects of health were neglected.

James Paul in his short essay *Medicine and Imperialism* puts forth an overall picture of the relationship between the two. He considers five "principal features of medical imperial politics— (1) physicians as covert diplomats; (2) physicians as propagandists and spies among colonial people; (3) medicine as a vehicle for imperialist propaganda in the metropolitan centre; (4) colonies as territories for medical sales and medical experimentation; (5) Medicine as a vehicle for establishing and maintaining the exploitative social relations." His analysis is, however, exclusively based on the colonial experience and it has to be seen as to whether and how many of these five features continue in post-colonial imperialism and whether any new features are added. (For example : the question of brain-drain) The distinctly new phase of imperialism after the World War II must be borne in mind. Many marxists mistake colonial imperialism in general and hence generalise from the colonial experience. James Paul's analysis tilts towards such misinterpretation. He however points out that the contradictions of "imperialist medicine" and hence the possibilities of revolutionary change. It would be worthwhile to study the relationship between imperialism and medicine in India, keeping in mind the five features discussed by James Paul.

The last article in this section traces the relationship between the military and medicine. It shows how medicine has on many occasions not been above nations, and how it has directly, and indirectly helped war-efforts. This much is not surprising. What is more startling is the conscious effort of invaders to use medical work to boost up the image of the conquering nation. Howard Levy has successfully shown with the help of quotations from military men how this occured in the case of the American Army in the fifties and the sixties, especially in the Vietnam War.

On the whole, the book is rich and wide-ranging in the historical material it contains which exposes the ideological role played by medicine in bourgeois society. It does not, however, show the correspondence between the different stages of the development of capitalist economy and the development of health and medicine. This is partly because of its character as a collection of essays. But that in itself cannot explain this weakness. Secondly, the contradictions in medicine in bourgeois society are no where posited clearly, emphatically. The analysis therefore can be misunderstood as an attack on medicine as such and not on its bourgeois form. Morever the possibility and necessity of revolutionary change does not emerge because of this failure to point out the contradictions in today's medicine. Though not a very systematic account in this sense, this collection of incisive and very absorbing pieces of historical analyses is one of the most important and useful additions to the marxist analysis of medicine in bourgeois society. It is essential reading for anybody wanting to understand the nature of medicine in capitalist society.

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved.

Each issue of the journal will focus on one theme, but it will also carry (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

Our forthcoming issues will focus on : Women and Health, Work and Health, Politics of Population Control, and Health and Imperialism.

If you wish to write on any of these issues do let us know immediately. We have to work three months ahead of the date of publication, which means that the issue on Women and Health is already being worked on. A full length article should not exceed 6,000 words. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We would also like to receive shorter articles, commentaries, views or reports. These need not be on the themes we have mentioned. These articles should not exceed 2,000 words. We will also be introducing a 'Letters' column, so please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be nealty typed in double spacing, on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions **in a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced on one side of the paper.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are working on issues of interest to you.

WORKING EDITORS

Please send me Socialist Health Review for one year (four issues). I am sending Rs. _____ as subscription and/or donation by MO/ Demand Draft/Cheque. (D D. and cheque in favour of Amar Jesani or Padma Prakash, and for cheque, Rs 5, if outside Bombay).

A Worker's Speech to a Doctor

We know what makes us ill
When we are ill we are told
That it's you who will heal us.

For ten years, we are told
You learned healing in fine schools
Built at the people's expense
And to get your knowledge
Spent a fortune.
So you must be able to heal.

Are you able to heal ?

When we come to you
Our rags are torn off us
And you listen all over our naked body.
One glance at our rags would
Tell you more. It is the same cause that wears
Our bodies and our clothes.

The pain in our shoulder comes
You say, from the damp; and this is also the reason
So tell us :

Where does the damp come from ?

Too much work and too little food
Make us feeble and thin
Your prescription says :
Put on more weight
You might as well tell a bullrush
Not to get wet
How much time can you give us ?
We see : one carpet in your flat costs
The fees you earn from
Five thousand consultations.

You'll no doubt say
You are innocent. The damp patch
On the walls of our flats
Tells the same story.

— Bertolt Brecht

ROOTS OF WOMEN'S ILL HEALTH

Power relations mediate all social life and as such, they not only determine our environment, but also define the way we react to it. Our definitions of health and illness depend on the characteristics of the society we live in and our location in it. In a society where commodity production is predominant as long as an individual can work productively or rather, as long as that labour is productive to the capitalist, the individual is considered healthy. Therefore, health services are directed at maintaining this minimum level of health below which the generation of surplus value would fall off (Schatzkin, 1978). In turn, this defines for the worker, the boundaries of ill health such that real health needs from the point of view of quality of life never get expressed. For, the fulfilment of these health needs would be contradictory to the needs of capital accumulation. The patterns of morbidity and mortality express and reflect this contradiction between real health needs of the worker and the level of health necessary for the generation of surplus value.

How does all this affect women? As a component of the labour foce, their needs are subordinated to the needs of capital. Further, a woman's traditional role is to reproduce and sustain labour power. This is the necessary function of women in society--- the maintenance and reproduction of the labour force, which in turn is necessary for the reproduction of capital. For a woman, the definition of health is determined by her ability to perform these functions. Just as in the workplace, the worker's health needs are subordinated to the needs of capital accumulation, women's health needs are subordinated to the need to maintain the work force at that level of health required for the generation of surplus value. Moreover, women as integral units of the family, are necessary not only for the reproduction of the working class, but also for reinforcing the ideological underpinnings of capitalism. Medical and health services are designed to keep women at an optimum level for the performance of these functions. **Thus, the needs of capitalist accumulation mediating through partiarchal relations suppress women's real health needs and their reproductive freedom.**

Medicine legitimates and rationalises social attitudes and notions about women (and men) whether they relate to their physiology or their social role. And since women's oppression is justified by their supposed biological inferiority, medicine obviously plays a very important role, in substantiating this myth. Medicine's 'model' of the normal human being is the upper/middle class male. This makes all women, by definition 'abnormal'! Menstruation becomes a disability, child birth an illness. Female physiology is considered a complication of the basic male physiology especially with reference to the reproductive (Rothman, 1979).

Two of the characteristic features of bourgeois medicine are its clinical paradigm and the dominant mechanistic model of the human body. This locates the cause of all ill-health entirely within the body, either as being due to the intervention of an outside agent or because of the malfunctioning of one or more 'parts' which comprise the human body. This means that women's complaints, if they are not caused by obvious external agents, must lie either in their 'aberrant' reproductive physiology (so different from the male) or in their peculiar female 'psyche'. Moreover, the models of 'normality' in medicine are those that are approved of by dominant ideology and are useful to bourgeois society. For women such a model is the ideal image of wife or mother. Not surprisingly, all health problems of women are seen in terms of how they might affect the fulfilment of that role.

Medicine, which is always articulated within a specific mode of production, contributes to the reproduction of that mode not only at the ideological but also at the economic and political levels. Thus the inappropriateness of medicine for women or its inaccessibility to the poor or to women is a characteristic feature of bourgeois medicine which serves to maintain and perpetuate the current relations of production and reproduction.

Any enquiry, discussion or analysis of health from a radical, marxist perspective must include an analysis of the women - and - health nexus. At the same time, no understanding of the women's status, their oppression and exploitation can be complete without a clear perception of the political and ideological roots of women's ill health.

The Women's Health Movement Abroad

In the '60s, the growing disenchantment of women with institutions and with social norms took the form of women's liberation movement. The

brought women together in consciousness raising groups where women for the first time began to exchange personal experiences and make women-to-women contacts that had been denied them. Among other things, this led to the realisation that their demeaning and dehumanising experience in the health system were not stray and personal incidents but the universal experience of all women. This has over the years generated several analyses of the medical system and has led to specific actions and programmes.

Elizabeth Fee (1970) characterises these in terms of three forms of social criticism, the liberal feminist, radical feminist and marxist feminist. Liberal feminist saw their main challenge as being destroying the myth of a biological basis of women's oppression. They demanded equal pay and equal opportunity for women but did not seriously challenge the social and economic hierarchy. They saw the medical system as reflecting the sexual hierarchy of society with a male monopoly of the upper levels and a predominance of women at the menial jobs at the lower levels. Their solution was centered on demanding a better representation of women at the upper levels, but did not question the hierarchical organisation of health care or of society.

Radical feminism demanded a fundamental, restructuring of society, its institutions and values. Many of these women had participated in student, civil rights and anti-war movements. Some had become disenchanted with left parties and official marxist view of feminism as being a form of bourgeois protest and with marxist analyses which appeared to be insufficient to explain women's situation adequately or provide a satisfactory theoretical understanding of the family, reproduction, sexuality. Radical feminism saw the patriarchal family as the major and most important oppressive force in society and a battle of the sexes as being of more consequence than the class struggle. They saw revolution as leading to an annihilation of sex differences. There was an outpouring of radical feminist analyses of society, of institutions and of politics in the late '60s and the '70s, all of which served to expose the operation of paternalist ideology and the structures of women's oppression in society.

Radical feminists saw the medical profession as imitating patriarchal society and were heavily critical of medical mysticism especially in the area of gynaecology and obstetrics. They worked to disseminate information and knowledge about medicine and specially about women's sexual and reproductive functions which had for so long been a monopoly of the doctors. This led to a strong movement against hospitalised childbirth in the US. Groups in many states of the US and in Britain and Europe set up women's health centres and self-help clinics as 'alternatives' to the dehumanised hospital centred medical systems. They provided for gynaecological examinations, and childbirth facilities as well as abortion services. Inevitably they have come into conflict with power groups and professional groups, but have survived and proliferated nevertheless.

It was mainly this current of feminist thought which gave rise to a number of significant books and pamphlets such as *Our Bodies Ourselves* (from the Boston Women's Health Book Collective), *Witches-Midwives and Nurses* and *Complaints and Disorders* (both by Barbara Ehrenreich and Deirdre English) and *Vaginal Politics* (by E Frankfort). This and other similar literature has been very influential in rejuvenating the interest of radical and marxist groups in the history, nature and ideology of science and medicine.

Marxist feminists saw their task as the combining of feminist consciousness with historical dialectical method of analysis. They saw patriarchy as both supporting and strengthening capitalism. At the same time they saw capitalism as providing the material condition for the future abolition of sexual distinction between man's work and women's work, but the realisation of these conditions being limited to the extent necessary for the survival of capitalism. "Capitalism... cannot free itself from dependence on sexism any more than it can transcend class oppression or the pursuit of private profit at the expense of the satisfaction of real human needs" (Fee, 1975).

Marxist feminists believe that no one characteristic of the medical system can be analysed in itself, but must only be seen in relation to the entire social structure and its institutions, and the economic order in which it is rooted. Thus, they see the fragmentation of capitalist medicine as a part and consequence of the ideology of medicine which sees the body in parts. They are also critical of the sexist bias of medicine and the emphasis on 'scientific' base which itself has an inherent class and sex bias. They see medicine as ignoring the social roots of illness.

Women's Health Issues in India

In India, women's health issues have not emerged as a major focus of activity or analyses within the women's movement. Women's groups are of course, aware of women's inaccessibility to health care services, the lack of reproductive freedom, sexual harassment of women patients (and of nurses) and to a lesser extent the operation of the sexist ideology

in medicine. But this has not led to a comprehensive theoretical understanding of women's health as a part of feminist theory. Nor has it generated concerted action programmes. There have been individual campaigns, such as the demand for a ban on estrogen-progesterone drugs for pregnancy testing and amniocentesis for sex determination. But while these, especially the latter, has given rise to significant debate and action, one cannot say that they have led to a better perspective of the role of medical technology in the oppression of women. The reason for this apparent uninterest in health issues perhaps lies in the historical and economic roots of the women's movement in India and needs to be examined.

This apathy towards health issues is even more significant when one recollects that rape was one of the earliest issues taken up by the women's movement. It would have been logical to suppose that this would have led to a discussion of broader questions of female sexuality, a realisation of how little women knew about their bodies and ultimately, to a questioning of the male monopoly of the information about women's bodies, its functioning in health and illness. This did not happen, although there was sporadic discussion about such matters as the 'technical' definition of rape and the relevance of injuries on a woman's body. Nor was there significant and sustained effort to provide 'alternative' medical aid to vicitims. Why did this not happen ? Was it because the medical system and the definitions promoted by it hold sway even among those who have little access to it ?

Health issues which would be of concern to Indian women are generally different from those which confronted feminists in the West in the late '60s and early'70s. For instance, by then in most countries of the West, the major achievements of medicine which produced visible and noticeable change had already taken place. The life expectancy had levelled out and there appeared to be after all, a maximum limit to human life. Together with this, the hospital-centred medical system had increasingly become dehumanised, authoritarian and expensive. The women's movement could successfully question the ethos of such a system and its value to women.

In the '70s in India, although the state health system was weak and inefficient, it was at least able to bring some relief, especially in acute illness and during crises. Moreover, by this time several groups, frustrated and disgusted with both the state systems and the rapacity of the private practitioners had set up 'alternative' health programmes in the rural areas. And many of these had made maternal and child health programmes their main focus. Undoubtedly, this brought about positive changes in women's (or rather maternal) health status. Therefore the women's movement in India had no immediate and concrete targets in the area of health The demand for birth control measures and abortion were two major areas of activity of the women's health movement in the West. In India, such measures were, in fact, being forced on women as part of a determined and massive family planning programme.

Further, the sex-wise mortality and morbidity picture in the West was and is quite different from the Indian. In the US, for instance, women show lower mortality and morbidity rates and also a greater frequency of contact with the medical system. Women there were concerned with countering the criticism that women were generally, hypochondriac, and in voicing concern and initiating action about the increasing consumption of tranquilisers and painkillers by women.

What then, are the issues which demand concerte action, research and discussion in India today? It is hardly necessary to point out that women's health status has been steadily declining. In 1901, the sex ratio (number of women to 1000 men) was 972 which declined to 930 in 1971. In almost every age group (except 10 to 14 years) until 34, the age-specific death rates are higher for women. Or in other words more than half the deaths among women occur before they are 35. According to one report, 20 per cent of all deaths among women in the age group 15-34 are because of childbirth and associated causes (SNDT 1981). However, maternal mortality is not the major cause of death among women in that age group. And yet most health programmes are directed only at reducing maternal mortality without any alteration of the accessibility of this group of women to general services.

Women have also been the major focus of family planning programmes. Most of the measures proposed and implemented — sterilisation, abortion, oral contraceptives, copper T, injectables — have affected women's health significantly, and even disastrously.

The changing patterns of economic development have put a heavy burden on women which is reflected in their health status. In a society where women hold a lower social status, any situation of deprivation is bound to affect women adversely. The marginalisation of farmers, landlessness and forced migration, temporary and permanent, have undoubtedly affected women's health and nutritional

status. The growth of the small and the cottage industries sector has depended heavily on female labour. And most of these do not come under the purview of any kind of safety legislation. Therefore, women have, in the last decade become exposed to new kind of health hazards. Added to this is the fact that women risk their lives in the performance of domestic labour. According to Rajni Kothari a woman spends approximately 73,000 hours on an average in the kitchen, most of which are environmentally harmful and unsafe (Raj and Patel, 1982).

The number of 'workers' among women is estimated to be only 20.01 per cent. But the Census definition of 'work' does not include cooking, collecting firewood, fetching water, etc. activities which take up half the energy expenditure of women. At the same time adult women eat consistently less than men and also much less than the recommended calorific allowances, which are themselves based on somewhat questionable assumptions. According to a recent survey carried out by the National Institute of Nutrition, Hyderabad, 60 per cent of the rural population is anaemic, most of this group being women. Malnutrition is not only aggravated by diseases but renders women more prone to illness. Ironically enough, although women suffer from illness more or at least as often as men, they seek help less often.

There is little hard-core data available to support any analysis of women's health status. And this itself is a telling comment on how unimportant women's health is. Nevertheless, there is sufficient evidence — experiences, personal observations—that women's health status presents an apalling, dismaying and deteriorating picture. In this, the second issue of SHR, we examine a few facets of this picture.

Sathyamala discusses the sexist ideology of medicine and its operation in the past and currently. She convincingly shows that the sexist ideology is so closely integrated with the theory and practice of medicine that it is difficult even to identify it, let alone accept it.

Our next offering is an article by Barbara Katz Rothman, reproduced from the book *Women : A feminist perspective* edited by Jo Freeman (1979) giving a slightly different theoretical explanation of the sexist bias. She sees sexism in medicine as a component of the mechanistic, positivist bourgeois medicine and calls for a critical examination of the medical mode of women's bodies and health.

Nirmala Sathe provides an overview of health issues in the women's movement in India.

Srilatha Batliwala writes on the energy-health-nutrition nexus with reference to women. This paper gives credence to the fact that the gap between expenditure for energy and intake of calories is large for women than for men. These data and the accompanying analyses gave for the first time, (when it was first presented) hard core information and statistics about some aspects of women s health status.

Meredeth Turshen's article is an extract from a book *Third World Medicine and Social Change* (editied by John Morgan and published by Lanham) which is just out. It analyses the nutrition-health complex with reference to women in Africa. It looks at the health situation of women from the perspective of Africa's changing economy. It seeks to show the linkages between political and economic measures, changes in cropping patterns, food imports, international loans and changes in land tenure, women's nutritional and health status.

Misuse of medical technology is at times, a sore topic of discussion. The use of amniocentesis for sex determination, aroused great deal of discussion a year ago. It was in fact, one of the few issues that women's groups took up all over the country and pressed for a ban on such tests being used indiscriminately. Vibhuti Patel concisely traces the major features of this debate and highlights the misuse of such medical technology which more often than not leads to female foeticide.

How healthy are workers in the drug industry? A large number of women are employed in the pharmaceutical industry , but there are few studies of their health status. Sujata Gotoskar, Rohini Banaji and Vijay Kanhere report a case-study of women workers manufacturing vasodilators. A drug such as this is prescribed to produce a definite physiological change in those who need it. What happens to normal women who have to breath in the powder day-in and day-out? This study, highlights the need to gather more information of the hazards women face at work places.

We wind up this issue with a review and report of 'health' problem which is currently facing the Kashtakari Sanghatana working among the adivasis in Dahanu in Maharashtra. And this is the torture of women 'bhutalis' (witches). The Sanghatana has attempted in this paper to locate the issue in a socio-economic perspective. Who is the witch? Why

(*Contd on Page 57*)

IS MEDICINE INHERENTLY SEXIST ?

c sathyamala

During the last twenty years, many feminists, activists and researchers have been taking a closer look at medicine. There is voluminous and irrefutable evidence that the medicine of the 19th and early 20th centuries incorporated and reinforced the sexist ideology in society. But does sexism operate in and through current medical practice in India? The author argues, that the teaching and practice of medicine here is strongly influenced by what happens in the West With extensive illustrations from popular textbooks and journals she shows how sexism in medicine operates just as strongly now as it did a hundred years ago. Additionally, campaigns such as the one promoting breast feeding continue to use outmoded and demeaning stereotype for women. This article is based on a paper written for the Medico Friend Circle's Annual Conference held in 1983, which focussed on 'Prejudice against women in the medical system.'

Medicine has played and continues to play a powerful role as a reinforcer and perpetuator of sexist ideology. It has the dubious distinction of shifting justification for sexism from religion to bio-medicine, thereby taking it out of the realm of prejudice and putting it within the confines of 'scientific' objectivity. The interpretations medicine offers are basically to legitimise the discrimination of women and their continued oppression under the guise of biological determinism.

The period of rapid industrialisation in the West witnessed the growth of the monopoly of the white middle-class male over medicine. This period also saw the emergence of new social norms which specified roles on the basis of sex and class. The upper-class women were expected to lead a sedentary life of enforced leisure with nothing more taxing than embroidery to keep them occupied, whereas the working-class women were forced to lead a life of hard physical labour. Although it was the working class women who were subjected to a host of illnesses, (a result of nutritional deficiencies and poor working and living conditions) it was the upper-class women whom medicine considered as inherently sick. "It was the wealth extracted in that harsh outside world that enabled a man to afford a totally leisured wife. She was the social ornament that proved a man's success, her idleness, her delicacy, her child-like ignorance of 'reality' gave a man the 'class' that money alone could not provide". (Ehrenreich and English, 1973).

The combined effects of enforced leisure, confinement and boredom led to the emergence of the cult of 'female invalidism' among the upper class women. To the medical men the 'sick' women of the upper classes were a godsend. Here was a patient, who was ill without being 'diseased', in obvious need of the ministrations of a medical man (like himself), compliant enough to obey every one of the doctor's demands, and wealthy enough to afford the prolonged treatment --- an ideal patient as it were. "As a businessman, the doctor had a direct interest in a social role for women that encouraged them to be sick; as a doctor he had an obligation to find the causes of female complaints. The result was that as a scientist he ended up proposing medical theories that were actually justifications of women's social roles". (Ehrenreich and English, 1973). The popular medical theory proposed was that women's inherent weakness rested on the physiological law of 'conservation of energy'. Each person had a fixed supply of vital energy and the different organs had to compete with each other for their share. Since a woman's life was centred around her reproductive organs it meant that these organs developed at the expense of all the other organs. The result of such distribution of energy left the woman strong enough to bear children, but weak in every other way. This theory implied that the woman could never be physically or intellectually superior to a man who did not lose out his energy on reproductive functions. As a further development of the theory, it was postulated that the ovaries were central to the woman's being. The ovaries determined the personality traits of the woman and these could range from irritability to insanity. In textbooks and in actual medical practice, doctors found uterine and ovarian problems behind every female complaint be they headaches, sore throat or tuberculosis.

Although all these could be dismissed as part of the deep medical ignorance of the times, it did not prevent the medical profession from carrying out treatment which were specifically designed to alter female behaviour. Treatment for female invalidism included isolation, prolonged rest, clitorectomy and ovariotomy. Ehrenreich and English point out that this was in effect a surveillance system through

which the doctors could detect the first signs of rebelliousness and could interpret them as symptoms of disease, and hence, curable.

But the theories and medications could not be applied to working-class women. They had neither the time nor the money to indulge in female invalidism and their labour was essential for the growth of capital. Medical theory came up with an explanation based on racial differences : These women (mostly blacks and immigrants from Europe) were congenitally inferior to the white Anglo-Saxon protestants in that they had smaller brains, larger muscles and a host of inherited social traits. They were considered to be free from uterine diseases and were supposed to have robust healthy babies. Although these working-class women were not 'sick' they were 'sickening' to other classes. They bred disease and were the reservoir of infection. The danger of coming in contact with working-class women was especially great for upper classes for they often worked as maids in the homes of the upper class and as prostitutes. Thus medical theory proposed two seperate biological reasons to explain and justify the social roles of these two classes.

Sexism in Current Medical Practice

It could be argued that all this took place in the distant past at a time when the scientific foundation of medicine was still being laid and that the content of medicine itself has changed since then. Such an argument would be valid only if it was possible to prove that the later devlopments in medicine were not influenced by sexist prejudices. But a review of medical literature reveals that sexism is still dominant in the interaction between 'medicine' women, and medicine still continues to rationalise and to dictate social norms to women.

It would have been difficult to substantiate these statements had they been made say, twenty years ago, because then the ultimate pronouncements on woman's 'nature' still came from the doctors. But the militant feminist movement in the west has been powerful enough to draw the attention of academicians to provide the much-needed data. The following quotes are taken from **studies conducted in US and in England and are relevant to India as well, for the teaching and practice of medicine is not very different and students follow the same textbooks.** Doctors continue to view women patients as hysterical, irrational and incapable of making decisions. ". . . . . women's illnesses are psychosomatic until proven otherwise".

"Following traditional linguistic convention, patients in most medical school lectures are referred

> *"Primary dysmenorrhoea is dismissed as being psychogenic, although it affects 50 percent of women"*

to exclusively by the male pronoun 'he'. There is, however a notable exception: in discussing a hypothetical patient whose disease is of psychogenic origin, the lecturer often automatically uses 'she'. For it is widely taught, both explicitly and implicitly, that women patients (when they receive notice at all) have uninteresting illnesses are unreliable historians and are beset by such emotionality that their symptoms are unlikely to reflect 'real' disease."

" Woman as compared to men are more likely to have their depression treated by drugs than to be helped to overcome the causes of their distress". (Howell, 1974)

Work up by physicians in response to five common complaints in a sample of 104 men and women - 52 married couples — were evaluated by chart audit. For the total group of complaints, back pain, headache, dizziness, chest pain and fatigue, the physicians' work ups were significantly more extensive for men than they were for women. These data tend to support the argument that male physicians take medical illness more seriously in men than in women. (Armitage et al, 1979)

Most complaints which are termed women's complaints (because they refer to their reproductive tracts) are often dismissed as being of purely psychogenic origin. Primary dysmenorrhoea is one such gynaecological complaint which though it affects about 50 per cent of women, is considered partly or wholly psychogenic. This is inspite of the fact that the origin of pain is still unknown.

"One gains little conviction in relation to most of the literature (regarding dysmenorrhoea) especially in respect of management. To illustrate an extreme, one recent study advises physicians not to trust empiric diagnoses of dysfunctional dysmenorrhoea, but to inspect the peritoneal cavity by culdoscope and to expect often to find free (menstrual ?) blood as the cause of the pain. Actually, one is finally driven to the conclusion that theories concerning intrinsic dysmenorrhoea in early menstruation are as conflicting as are countless methods and medications which are claimed as being helpful. Hardly, a day or a medical journal, goes by which does not offer a new near-panacea whose rationale conflicts with many

others. **It reflects more essentially the psychosomatic ineffectiveness of the proscribing physician, and in general the results are not superior to our sage advices at the beginning of the century"** (Jones).

The psychogenic theory of primary dysmenorrhoea however is very definite : "It is generally acknowledged that this condition, is much more frequent in the highstrung, nervous or neurotic female than in her stabler sister." (Lennane and Lennane 1973).

"Faulty outlook leading to an exaggeration of minor discomfort . . . . may even be an excuse to avoid doing something that is disliked". Or more simply, "The pain is always secondary to an emotional problem." (Lennane and Lennane 1973).

In refuting these theories Jean Lennane and John Lennane have this to say : "There is no valid basis for this attitude. These authors are not referring merely to the effect that the personality of the patient may have on the amount of suffering or complaints occurring in any organic illness, but are implying or directly stating, that the patients' faulty outlook is causing the condition.

"If the pain is the result of 'faulty outlook' one would expect it to start at the time of the initial psychic shock (menarche), and not two to four years later. The pain is dependent on the occurrence of ovulation and is reliably and usually completely removed by suppression of ovulation (92 per cent of severe cases in one study) Perhaps the few who do not respond to ovulation suppression might be psychologically disturbed, but in practice, psychosomatic study and psychometric tests do not confirm this hypothesis. Scientific supporting evidence is completely absent e. g. a prospective study of pubescent girls, or of menstruating girls who were not yet ovulating. Evidence when offered, is scanty. **'A dysmenorrhoic mother usually has a dysmenorrhoic daughter'** which, if true (no statistical confirmation is offered), would more usually be taken to indicate a hereditary factor.

"The attitude to treatment may also be unusual.. 'very little can be done for the patient who prefers to use menstrual symptoms as a monthly refuge from responsibility and effort'. The patient with visceral colic is treated with rest and relief of pain; the patient who persists in having severe dysmenorrhoea may be denied both." (Lennane and Lennane, 1973)

The following quote also shows how women's gynaecological complaints are seen as unimportant and not worthy of medical attention. "Majority of the women in our country are housewives. In most

"Mistaken and misleading beliefs about female sexuality continued to dominate medical theories until the late 70s"

of the other countries women do as much office work as men and in addition do the duties of housewives. Thus Indian women have more 'spare time'. Since majority of them have no other activities or hobbies and do not do any reading (being uneducated) **they spend most of their spare time concentrating on their vaginal discharge"**. (emphasis ours) (Kapoor, 1976). The underlying attitude that will be encouraged in general practitioners is self-evident. It is also significant that leucorrhoea (vaginal white discharge) is the only common gynec problem discussed in the book.

In fact, it is not too farfetched to say that almost every second gynaecological complaint is viewed with suspicion as being fictitious and just a figment of the imagination. Here is what Lennane and Lennane say with regard to nausea of pregnancy : "A well-defined clinical entity occurring in 75 to 88 per cent of pregnant women. The exact cause remains unknown. The condition is nevertheless commonly held to be partly or wholly psychogenic again without any scientific supporting evidence. Few will deny that the psychogenic factor is of prime importance, and it is probable that many adjustments demanded of the newly-pregnant woman impose a mild condition of stress coupled with an irrationally exaggerated fear of the obstetric hazards confronting her, especially that of producing an abnormal child. Classified with the neuroses (nausea of pregnancy) may indicate resentment, ambivalence and inadequacy in women ill-prepared for motherhood" . . . . . " Nearly all pregnant women see a doctor and to classify up to 88 per cent of patients with a particular organic condition (pregnancy) as neurotic is unusual in the extreme" . . "its severity in multiple pregnancy and hydatidiform mole contradict the neurosis theory, unless it is postulated that the patient can subconsciously and definitely diagnose these conditions as early as the fourth week" (Lennane and Lennane, 1973).

Female sexuality has always been a source of concern in all patriarchal societies. Medical theories of the late 19th and early 20th century drew a rigid distinction between reproductivity and sexuality. It was believed that the development of reproductive powers and of the maternal instincts could only take place when sexuality itself was suppressed. Women

were told (by medical theoreticians) that sexual feelings were 'unnatural, unwomanly pathological and probably detrimental to the supreme function of reproduction". These beliefs continued to dominate medical theories till as late as the 'seventies, even after Master's and Johnson's findings had revolutionised the understanding of female sexuality. According to Scully and Bart (1973) who reviewed 27 general gynaecological textbooks published in the US from 1943 to 1972: "... examination of gynaecological textbooks, one of the primary professional socialisation agents for practitioners in the field, revealed a persistent bias towards a greater concern with the patient's husband than with the patient herself. Women are consistently described as anatomically destined to be happy. So gynaecology appears to be another of the forces committed to maintaining traditional sex role stereotypes, in the interest of men and from a male perspective."

In the textbooks published between 1963-72: " Eight (of the textbooks) continued to state, contrary to Master's and Johnson's findings, that the male sex drive was stronger and six still maintained that procreation was the major function of sex for the female. Two said that most women were 'frigid' and another stated that one-third were sexually unresponsive..... when they (the book) deal with the subject (sex role) the traditional female sex role is preferred. Thus Jeffcoate states 'An important feature of sex desire in the man is the urge to dominate the women and subjugate her to his will; in the women, acquiescence to the masterful takes a high place'. In 1971 we read: 'the traits that compose the core of the female personality are feminine narcissism, masochism and passivity '... A 1970 text states, 'The frequency of intercourse depends entirely upon the male sex drive. The bride should be advised to allow her husband's sex drive to set their pace and she should attempt to gear hers satisfactorily to his. If she finds, after several months or years that this is not possible, she be advised to consult her physician as soon as she realises there is a real problem'. The gynaecologist's self-image as helpful to women combined with unbelievable condescension is epitomised in this remark: "If like all human beings he (the gynaecologist) is made in the image of the Almighty and if he is kind, then his kindness and concern for his patient may provide her with a glimpse of God's image."

Medical attitudes have changed little in spite of the criticisms which have been the outcome of the feminist movement. A recent example is the breast feeding campaign which has merely incorporated the new attitude of society towards women,

"The advocates of the breast feeding campaign reinforce the idea of the main role of women being to reproduce and nourish at the cost of self"

but has not changed its fundamental sexist ideology.

For many years the infant formula companies had peddled breast milk substitutes as an expression of mother's love They had played upon the image of women as sex objects who in order to be desirable had to be depilated, deodorised, and have well-shaped and firm breasts. The counter propoganda (of the breast feeding campaign) tries to allay the fears of the mother about the shape of her breast by reassuring her that breast feeding will, in fact, make her more shapely.

"Contrary to the old wives's tales that nursing makes breasts sag (age and gravity do that), breast feeding actually helps women to get their bodies back in shape after childbirth. It helps the uterus return to its pre-pregnancy condition and facilitates loss of excess weight gained during pregnancy. It promotes a deep feeling of warmth and attachment between mother and baby, and many women report the physical sensations of breast feeding are pleasurable" (UNICEF, 1981). The issue is not whether the technical content of the quote is correct or not, but that the images it uses and reinforces are as sexist as 'organised' commercial advertisement. The advocates of this campaign also reinforce the idea of the main role of women as being to reproduce and to nourish at the cost of self.

' Lactation offers the opportunity of giving 'self.' to feed an infant, instead of feeding through the medium of the substitute glass bottle, rubber nipple and compounded baby formula. To this end successful lactation is indeed, a worthy and noble goal for the physician to inspire" (Applebaum, 1970). And further,

"The remarkable ability of poor women to breast feed their babies for prolonged periods is the most redeeming feature in an otherwise bleak nutritional status of many developing countries" (Gopalan, quoted UNICEF)

Conclusions

A woman is by definition 'emotional'. For long it was believed that a woman's emotions were controlled by her womb and a disturbance in the womb

led to a hysterical state. Modern thinking has reversed this understanding. It is believed now that emotions acting through hypothalamus effect menstrual function considerably.

The process of professionalisation includes learning attitudes about work, about relations with colleagues and about patients or clients. In medicne these attituides are strongly coloured by a demeaning regard for women. For, after all, such attitudes about women are pervasive in society and moreover the medical profession has been virtually a male monopoly. This may be disputed in India since the majority of gynaecologists here are women. Unfortunately, they too have imbibed the sexist values in society. We are all products of our cultural expectations---- and our culture devalues women.

The answer does not lie in doing away with gynaecologists. The more mature way would be : (i) to recognise inadequacies that exist in our knowledge and be more open and receptive to women's personal experiences; (ii) to redirect research priorities and focus on problems that women consider as important; (iii) to end the medical monopoly of knowledge about women's physiology, their illnesses. Only then can we hope that medicine will serve those who need it most.

does witch-hunting take place with greater frequency during certain seasons? There are no simple answers. This article looks at the entire complex fabric of the adivasi's way of life, the status of women, and how factors such as deforestation, modern diseases, increasing unemployment and impoverishment and a deterioration and disappearance of trbial knowledge of medicine may be generating a set of circumstances which could perpetuate and strengthen the belief in the bhutalis and thus lead to increasing persecution of women. We especially ask readers to respond to this article.

Our focus throughout the issue is on women as consumers of health care. Women also comprise a large proportion of the providers of health care and we hope to devote a seperate issue to the topic sometime. We hope you find this glimpse of the many health issues which concerrn women, insteresting.

WOMEN, HEALTH AND MEDICINE

barbara katz rothman

Until pregnancy and childbirth were defined as medical events, midwifery was in no sense a branch, area or interest of medicine as a profession. The expansion of scientific medicine converted normal physical changes of pregnancy and others into medical problems devoid of their larger socio-emotional content. The displacement of the midwife by the male obstetrician resulted not from any ideological struggle or 'scientific' advancement but from the control that physicians exercised through their professional associations. The treatment of the body as a machine and the lesser functional importance assigned to women constituted a basis for exercising the overt social control over women through the surgical removal of her various sexual organs and by creating physical deformities in her. The author argues that the alternative to the mechanical model of taking the female system as a complication of so-called biological stability of the non-cycling male, is to take the female as working norm for the female system.

This article is reproduced from "Women : A feminist perspective" by Joe Freeman (Ed), Mayfield Publishing Co. 1979.

Women are not only people : *woman* is a subject one can study, even specialize in within medicine. Obstetricians and gynecologists are medicine's and perhaps society's generally recognized "experts" on the subject of women, especially women's bodies: our health, reproductive functioning, and sexuality.[1] Obstetrics is the branch of medicine concerning the care of women during pregnancy, labor, and the time surrounding childbirth,[2] similar in some ways to midwifery. Gynecology is the "science of the diseases of women, especially those affecting the sex organs."[3] There is no comparable "science" of the study of men, *their* diseases and/or reproductive functions. An attempt by urologists in 1819 to develop an "andrology" specialty came to nothing.[4]

At its simplest, we can think of a medical specialty as arising out of pre-existing needs. People have heart attacks : the medical specialty of cardiology develops. Or the amount of knowledge generated in a field grows so enormously that no one person can hope to master it all: physicians "carve out" their own areas of specialization. Increasing knowledge about cancer thus led to the specialty of oncology, and subspecialities within oncology.

But the development of a medical specialty is not necessarily the creation of a key for an already existing lock. Medical "needs" do not necessarily predate the specialty, even though the specialty is presumably organized to meet those needs. This has been made quite clear in the work of Thomas Szaz on the relatively recent expansion of medicine into such "social problem" areas as alcoholism, gambling and suicide.[5] Medicine doesn't have the "cures" for these problems but by defining them in medical terms, as sickness, the physician gains political control over the societal response: punishment becomes "treatment ', desired or not, successful or not. Similarly, medical control over childbirth, lactation, menopause, and other women's health issues was not based on superior ability to deal with these concerns.

The case of Jacoba Felice de Almania, a woman tried for the illegal practice of medicine in 1322 illustrates this point. In her defense Jacoba Felice de Almania had witnesses who testified that she never charged unless she cured, and that her cures were successful where other "legal" (male) practitioners had failed. However, since she had not attended a medical school (medical schools being closed to women) she was not licensed to practice medicine. That she saw women who did not want to go to a male practitioner, that she was successful did not matter. "Efficacy of treatment was not the criteria for determining who was or was not a legitimate medical practitioner, but the educational requirements and membership in the faculty of an organized group were the most important factors."[6] In essence, what professional control over medicine says is, "We may not be able to help you, but we are the only ones qualified to try."

Vern Bullough, in his analysis of the development of medicine as a profession, writes that during the middle ages, "One obvious group outside of the control of the university physician was the midwife, but during the period under study the university physician generally ignored this whole *area of medicine*. Midwives might or might not be qualified, but this *was not a matter of public concern* (emphasis added)".[7] More accurately, one might state not that physicians ignored this "area of medicine," but that midwifery and its concerns were outside of medicine, just as matters that were

undoubtedly of concern *to women* existed outside of the "public" concern. Until pregnancy and childbirth were defined as medical events, midwifery was in no sense a branch, area, or interest of medicine as a profession.

Medical expansion into the area of childbirth began before the development of asepsis, surgical techniques, anesthesia; any of what we now consider the contributions of obstetrics. And yet, even without the technology, by the beginning of the nineteenth century medicine had begun the redefinition of childbirth from a family or religous event to a medical one, needing medical presence for its safe conduct.[8]

Midwives treated childbirth in the larger context of women's lives. Midwives did not and do not deliver babies. They teach women how to give birth. Brack has called the role of midwife "total" —she helped in the socialization of the mother to her new status, both as teacher and as role model. "The midwife's relation to the woman was both diffuse and affective, while the physician role demanded specificity and affective neutrality".[9] Midwives taught how to birth babies, how to nurse them, how to care for the babies and for the mother's own body. Physicians deliver babies and move on. The physician "isolated the laboring woman and her delivery of the infant from the rest of the childbearing experience, and defined it as a medical and surgical event which required specialized knowledge."[10] As one modern nurse—midwife has said of obstetrics residents : "They want us to stay with the woman in labor and just call them when she's ready to deliver. To them, that's the whole thing."

At the time that physicians were taking over control of childbirth, it is virtually unarguable that the non-interventionist, supportive techniques of the midwives were safer for both the birthing woman and her baby. The physicians' approaches included bleeding to "syncope" (until the woman fainted), tobacco infusion enemas, frequent non-sterile examinations, and other surgical and chemical interventions.[11] In the 1910's and 20's, as American physicians successfully ousted midwives, the midwives' safety records remained better than the physicians. In Newark a midwifery program in 1914-16 achieved maternal mortality rates as low as 1.7 per thousand, while in Boston, where midwives were banned, the rates were 6.5 per 1000. Similarly, infant mortality rates in Newark were 8.5 per 1000 contrasted with 37.4 in Boston.[12] In Washington, as the percentage of births reported by midwives shrank from 50 percent in 1903 to 15 percent in 1912, infant mortality in the first day, first week, and first month of life all increased. New York's dwindling corps of midwives did significantly better than did New York doctors in preventing both stillbirths and post—partum infection.[13]

"... midwifery and its concerns were outside of medicine, just as matters that were undoubtedly of concern to women existed outside of the public concern".

The physician's separation of the "delivery" of the baby from its larger socio-emotional context has its roots as far back as Rene Descartes concept of mind-body dualism. To Descartes, the body was a machine whose structure and operation falls within the province of human knowledge, as distinguished from the mind which God alone can know. Though even the Hippocratic principles state that the mind and body should be considered together, "Experience shows that most physicians . . . irrespective of their professional activites and philosophical views on the nature of the mind, behave in practice as if they were still Cartesian dualists. Their conservative attitudes are largely a matter of practical convenience."[14]

The medical models used for convenience are that diseases are the bad-guys which the good-guy medications can take care of; that the body breaks down and needs repair; that repair can be done in the hospital like a car in the shop; and that once "fixed," the person can be returned to the community. The earliest models were largely mechanical; later models worked more with chemistry; and newer more sophisticated medical writing describes computer-like programming; but the basic points remain the same. It was a useful model when dealing with the problems facing medicine at the turn of the century : primarily bacterial and viral disease-causing agents and simple accidents and trauma. It has never worked well for understanding the problems that women face in dealing with doctors, including the experience of childbirth. While midwifery was learned by apprentice, doctors were instructed in the use of forceps, as well as techniques of normal delivery, by "book learning," by discussion, the use of wooden models, and infrequently by watching another doctor at work. Wertz, in her study of the development of obstetrics, has pointed out that "By regarding the female body as a machine, European doctors found that they could measure the birth canal and predict whether or not the child could pass through.'[15] Stories of women delivering while their doctors scrubbed for a Caesarian section were told, probably

«... the female gonads were removed not when women were «too female« that is, too passive or dependent, but when women were too masculine-assertive, aggressive, unruly...»

with much relish, and similar stories continue to be part of the lore of midwifery. Among the stories midwives tell each other are the tales of women who were told that they could never deliver vaginally, and then went on to have normal births of oversized babies.

In the nineteenth and early twentieth centuries midwives and physicians were in direct competition for patients, and not only for their fees. Newer, more clinically oriented medical training demanded "teaching material," so that even the immigrant and poor women were desired as patients. [15] The displacement of the midwife by the male obstetrician can be better understood in terms of this competition than as an ideological struggle or as "scientific advancement." Physicians, unlike the unorganized, disenfranchised midwives, had access to the power of the state through their professional associations. They were thus able to control licensing legislation, in state after state restricting the midwife's sphere of activity and imposing legal sanctions against her.[17]

The legislative changes were backed up by the attempt to win public disapproval for midwifery and support for obstetrics. Physicians accused midwives of ignorance and incompetence, and attacked midwifery practices as "meddlesome." Rather than upgrading the midwives and teaching the skills physicians thought necessary, the profession of medicine refused to train women either as midwives or as physicians. [18] Physicians argued repeatedly that medicine was the appropriate profession to handle birth because "normal pregnancy and parturition are exceptions and to consider them to be normal physiologic conditions was a fallacy." [19] Childbirth became redefined as a medical rather than a social event, and the roles and care surrounding it were reorganized to suit medical needs.[20]

Once professional dominance was established in the area of childbirth, obstetrics rapidly expanded into the relatively more sophisticated area of gynecology. The great obstetricians of the nineteenth century were invariably gynecologists [21] (and of course all men). Among other effects, this linking of obstetrics and gynecology further reinforced the obstetrical orientation toward pathology.

One of the earliest uses of the developing field of gynecology was the overt social control of women through surgical removal of various of her sexual organs. Surgical removal of the clitoris (clitoridectomy) or less dramatically, its foreskin (circumcision) and removal of the ovaries (oopherectomy or castration) were used to check women's "mental disorders." The first gynecologist to do a clitoridectomy was an Englishman, in 1858. [22] In England, the procedure was harshly criticised, and not repeated by others after the death of the originator in 1860. In America, however, clitoridectomies were done regularly from the late 1960's through till at least 1904 [23] and then sporadically until as recently as the late 1940's. [24] The procedure was used to terminate sexual desire or sexual behavior something deemed pathological in women. Circumcisions were done on women of all ages to stop masturbation up until at least 1937.[25]

More widespread than clitoridectomies or circumcisions were oopherectomies for psychological "disorders". Interestingly the female gonads were removed not when women were "too female" — i.e., too passive or dependent, but when women were too masculine—assertive, aggressive, "unruly." Oopherectomies for "psychiatric" reasons were done in America between 1872 and 1946. [26] (By the 1940's perfrontal lobotomies were gaining acceptance as psychosurgery.)

The developing medical control of women was not limited to extreme cures for psychiatric problems. The physical health and stability of even the most well-adjusted, lady-like women was questioned. Simply by virtue of gender, women were (and are) subject to illness labeling.

One explanation for women's vulnerability to illness labeling lies in the functionalist approach to the sociology of health. Talcott Parsons has pointed out that it is a functional requirement of any social system that there be a basic level of health of its members.[27] Any definition of illness that is too lenient would disqualify too many people from fulfilling their functions and would impose severe strains on the social system. System changes, such as war, can make changes in standards of health and illness generally set for members. This works on an individual level as well, standards of health and illness being related to social demands, a mild headache will excuse a student from attending class, but not from taking final exams. A logical extension of this is that the less valued a person or group's contribution to society, the more easily they are labeled ill.

Women are not always seen as functional members of society, as people doing important

things. This has historically and cross—culturally been especially true of the women of the upper classes in patriarchal societies, where it is a mark of status for a man to be able to afford to keep a wife who is not performing any useful function. A clear, if horrifying, example of this is the traditional Chinese practice of foot-binding. By crippling girls, men were able to show that they could afford to have wives and daughters who do nothing. It is a particularly disturbing example of conspicuous consumption. But we do not have to turn to faraway places to see women defined as useless. In Ehrenreich and English's historical analysis of the woman patient *Complaints and Disorders*, they speak of the late nineteenth and early twentieth century "lady of leisure." "She was the social ornament that proved a man's success; her idleness, her delicacy, her childlike ignorance of 'reality' gave a man the 'class' that money alone could not provide."[28]

The practice of creating physical deformity in women can be seen in our history as well. A woman researcher who studied menstrual problems among college women between 1890 and 1920 found that women in the earlier period probably were somewhat incapacitated by menstruation, just as the gynecologists of the day were claiming. However, she did not attribute the menstrual problems to women's "inherent disabilities" or "overgrowth of the intellect" as did the male physicians. She related it to dress styles. Women in the 1890's carried some fifteen pounds of skirts and petticoats, hanging from a tightly corseted waist. As skirts got lighter and waists were allowed to be larger, menstruation ceased to be the problem it had been.[29] In the interest of science, women might try the experiment of buckling themselves into a painfully small belt and hanging a fifteen pound weight from it. One might expect weakness, fatigue, shortness of breath, even fainting: all the physical symptoms of women's "inherent" disability. And consider further the effects of bleeding as a treatment for the problem.

It follows from Parson's analysis that in addition to actually creating physical disability (the bound feet of the Chinese, the deforming corsetry of our own histrory), women were more easily *defined* as sick when they were not seen as functional social members. At the same time in our history that the upper class women were "delicate", "sickly" and "frail," the working class women were well enough to perform the physical labor of housework, both their own and the upper classes as well as to work in the factories and fields. Because "...however sick or tired working class women might have been, they certainly did not have the time or money to support a cult of invalidism. Employers gave no time off for pregnancy or recovery from childbirth, much less for menstrual periods, though the wives of these same employers often retired to bed on all these occasions."[30] The working class women were seen as strong and healthy, and for them, pregnancy, menstruation, and menopause were not allowed to be incapacitating.

These two themes: **the treatment of the body as a machine, and the lesser functional importance assigned to women, still account for much of the medical treatment of women.**

Contemporary physicians do not usually speak of the normal female reproductive function as diseases. The exception, to be discussed below, is menopause. The other specifically female reproductive functions—menstruation, pregnancy, childbirth, and lactation—are regularly asserted in medical texts to be normal and healthy phenomena. However, these statements are made within the context of teaching the medical "management," "care," "supervision," and "treatment" of each of these 'conditions."

Understood in limited mechanical terms, each of these normal female conditions or happenings is a complication, stress on an otherwise normal system. Medicine has fared no better than any other discipline in arriving at a working model of women that does not take men as the comparative norm.

For example, while menstruation is no longer viewed as a disease, it is seen as a complication in the female system, contrasted to the reputed biologic stability of the supposedly noncycling male.[31] As recently as 1961 the American Journal of Obstetrics and Gynecology was still referring to women's "inherent disabilities" in explanations of menstruation:

> Women are known to suffer at least some inconvenience during certain phases of the reproductive cycle, and often with considerable mental and physical distress. Woman's awareness of her inherent disabilities is thought to create added mental and in turn physical changes in the total body response, and there result problems that concern the physician who must deal with them.[32]

Research on contraception displays the same mechanistic biases. The claim has been made that contraceptive research has concentrated on the female rather than the male because of the sheer number of potentially vulnerable links in the female chain of reproductive events.[33] Reproduction is

«Reproduction is dealt with not as a complicated organic process, but as a series of discrete points, like stations on an assembly line, with more for female than for male».

clearly a more complicated process for the female than the male. While we might claim that it is safer to intefrere in a simpler process, medicine has tended to view the number of points in the female reproductive process as distinct entities. Reproduction is dealt with not as a complicated organic process but as a series of discrete points, like stations on an assembly line, with more for female than for male.

The alternative to taking the female system as a complication of the "basic" or "simpler" male system is of course to take female as the working norm. In this approach, a pregnant woman is compared only to pregnant women, a lactating breast compared only to other lactating breasts. Pregnancy, lactation, etc. are accepted not only as nominally healthy variations, but as truly normal states. To take the example of pregnancy, women *are* pregnant; it's not something they "have" or "catch" or even "contain". Pregnancy involves physical change; they are not, as medical texts frequently call them, "symptoms" of pregnancy. Pregnancy is not a disease; its changes are no more "symptoms" than the growth spurt or development of pubic hair are "symptomatic" of puberty. There may be diseases or complications of pregnancy, but the pregnancy itself is neither disease nor complication.

In contrast, the working model of pregnancy that medicine has arrived at is that a pregnant woman is a woman with an insulated parasitic capsule growing inside. The pregnancy, while physically located within the woman, is still seen as "external" to her, not a part of her. The capsule within has been seen as virtually omniscient and omnipotent, reaching out and taking what it needs from the mother-host, at her expense if necessary while protected from all that is bad or harmful.

The pregnancy, in this medical model, is almost entirely a mechanical event in the mother. She differs from the nonpregnant only in the presence of this thing growing inside her. Difference other than the mechanical are accordingly seen as symptoms to be treated, so that the woman can be kept as "normal" as possible through the "stress" of the pregnancy. Pregnancy is not necessarily inherently unhealthy in this model, but it is frequently associated with changes other than the growth of the uterus and its contents, and these changes are seen as unhealthy. For example, haemoglobin (iron) is lower in pregnant women than nonpregnant, making pregnant women appear (by non-pregnant standards) anemic. They are then treated for this anemia with iron supplements. Water retention, or edema, is greater in pregnant women than non-pregnant, and they are treated with limits placed on their salt intake and with diuretics. Pregnant women tend to gain weight over that accounted for by the fetus, placenta and amniotic fluid. They are treated for this weight gain with strict diets, sometimes even with "diet pills". And knowing that these changes are likely to occur in pregnant women, American doctors have tried to treat all pregnant women with iron supplements, limits on salt and calorie intake, and many with diuretics, in the name of "preventive medicine".

What is particularly important to note is that these "treatments" of entirely normal phenomena are frequently not perceived by the medical profession as interventions or disruptions. Rather, the physician sees himself as assisting nature, restoring the woman to normality. Bogden, in her study of the development of obstetrics, reports that an 1800's non-interventionist physician, as opposed to a "regular" physician, would give a laboring woman a catheter, some castor oil or milk of magnesia, bleed her a pint or so, administer ergot, use poultices to blister her, and "Any of these therapies would be administered in the interests of setting the parturient up for an easier, less painful labor and delivery, while still holding to the belief that the physician was letting nature take its course." [34] Wertz says that currently medicine has redefined "natural childbirth" in response to consumer demand for it to include any of the following techniques : spinal or epidural anesthesia, inhalation anesthesia in the second stage of labor, forceps, epesiotomy, induced labor. [35] Each of these techniques increases the risk of childbirth for mothers and babies. [36] Under the title "Normal Delivery," an obstetric teaching film purports to show "the use of various drugs and procedures used to facilitate normal delivery." Another "Normal Delivery" film is 'a demonstration of a normal, spontaneous delivery: including a paracervical block, epesiotomy . . . ."

The use of estrogens provides an even better example of how medicine views the body as a machine that can be "run" or "managed" without being changed. Estrogens are female hormones; in medicine they are seen as femininty in a jar. In the widely selling *Feminin Forever*, Dr. Robert A. Wilson,

«The model of the body as a machine, which can be regulated, controlled, and «managed» by medical treatments, is not working. «Feminity» or physical »femaleness« is not something that comes in a jar and can be manipulated».

pushing "estrogen replacement the rapy" for all menopausal women, calls estrogen levels as detected by examination of cells from the vagina, a woman's "femininity index." As estrogen levels naturally drop off after menopause a women is according to Dr. Wilson, losing her "femininity. Interestingly, estrogen levels are also quite low while a woman is breast-feeding, something not usually socially linked to a "loss of femininity."

Menopause remains the one normal female process that is so overtly referred to as a "disease', in the medical literature. To some physicians, menopause is a *deficiency disease*, and the use of estrogen restoring the woman to her "normal" condition. Here we must reconsider the question of women's functional importance in the social system. Middle-aged housewives have been called the last of the "lady of leisure," having outlived their social usefulness as wife-mothers, and having been allowed no alternatives. While oopherectomies and clitorectomies are no longer being done on upper class women as they were a hundred years ago, to "cure" all kinds of dubious "ills," older women are having hysterectomies, (surgical removal of the uterus) at alarming rates. [3] Much more typical of modern medicine, however, is the use of chemical rather than surgical "therapy." Because the social changes and demands for readjustment of middle age roughly coincide with the time of menopause, menopause becomes the "illness" for which women can be treated.

Estrogens have been used in virtually every stage of the female reproductive cycle, and usually with the argument that they return the woman to normal or are a "natural" treatment. Estrogens are used in puberty, to keep girls from getting "unnaturally" tall; to treat painful menstruation; as contraception, supposedly mimicing pregnancy; as a chemical abortion in the "morning after" pill; to replace supposedly missing hormones and thus to prevent miscarriages; to dry up milk and return women to "normal" nonlactating state and in menopause to return women to the "normal" cycling state. For all the claims of normality and "natural" treatment, at this writing approximately half of these uses of estrogens have been shown to cause cancer. The use of estrogens in pregnancy was the first to be proven carcinogenic: daughters of women who had taken estrogens (notably DES, a particular synthetic estrogen) are at risk for the development of a rare cancer of the vagina [10] The sequential birth control pill was taken off the market as the danger of cancer of the lining of the uterus (endometrial cancer) become known, and similarly estrogens taken in menopause have been shown to increase the risk of endometrial cancer by as much as fourteen times after seven years of use. [21]

The model of the body as a machine, which can be regulated, controlled, and "managed" by medical treatments, is not working. "Femininity" or physical "femaleness" is not something that comes in a jar and can be manipulated.

Nor are women accepting the relegation to secondary functional importance, as wives and mothers of men. In rejecting the viewpoint that we bear men's children for them, we are reclaiming our bodies. When pregnancy is seen not as the presence of a (man's) fetus in a woman, but as a condition of the woman herself, attitudes toward contraception, infertility, abortion, and childbirth all change. When pregnancy is perceived as a condition of the woman then abortion, for example, is primarily a response to that condition.

The women's health movement has grown as an important part of the women's liberation movement. In some of its work, the movement has been geared toward consumerism within medicine, seeking better medical care and a wide range of services for women. While better trained, more knowledgeable and more *humane* physicians are a high priority, what the self-help and lay midwifery groups are doing goes much deeper than that. I believe that these women are reconstructing the pre-obstetrics and gynecology model of women's health. They are redefining women's health in fundamentally women's terms.

Women's self-help groups and clinics are teaching women how to examine their own bodies, not in the never-ending search for pathology in which physicians are trained, but to learn more about health. Medical technology and physicians are clearly useful in treating illness, but do we really want physicians to be "treating" health? It is entirely possible for a woman to fit herself for a diaphragm, do a pap smear and a breast examination (all with help and instruction if she needs it) and never adopt the "patient" role. It is also possible for a woman to go through a pregnancy and birth he

baby with good, knowledgeable, *caring* help, but without becoming a "patient" under the "supervision" of a physician.

Redefining normality within the context of the female reproductive sytstem will take time. We have all been imbued with the medical model of women's bodies and health and it is hard to work past that. Redefining women in women's terms is not a problem unique to health. It is an esential feminist issue.

Books in Print

Rational Drug Therapy : The Arogya Dakshata Mandal, 1913 Sadashiv Peth, Pune 411 030 is to publish in August, 1984 a booklet highlighting recent advances in the treatment of common dieases, rational approach to treatment, side effects of drugs, clinical diagnosis of common diseases etc. This is meant to act as a physician's desk reference for day-to-day practice. For further information write to Dr. A R. Patwardhan at the above address.

The Mandal also publishes a monthly information sheet the *Pune Journal of Continuing Health Education which* is designed to 'present scientific information and opinion to the medical profession to stimulate thought and further invistigation.' Subscription rate : Rs. 10 a year.

Book News

Our Jobs, Our Health : A woman's guide to occupational health and safety, Boston Women's Health Book Collective, Boston USA: The book shows how to recognise hazards in the work place It provides basic information about toxic chemical stress, job design, cancer and hazard control. The section of reproductive issues in the work place describes how workplace conditions can damage the reproductive health of both men and women. Finally it discusses legal rights and some strategies that can be used to win health and safety improvements in the work place. "WOMEN'S HEALTH IS WOMEN'S CONCERN"
A Brief Overview of Health Issues in the Women's Movement

nirmala sathe

Women's health status is closely linked to their social status. Even though the 'ideal' woman is supposed to look weak and delicate, she has to be able to perform all the domestic tasks necessary for the sustenance of the family. Her major role in society is that of a reproductive machine. The feminist movement aims at uniting women to raise their voices against the oppression of these stereotypes. Logically then, health issues concerning women must form an integral part of the women's movement. Why has the movement been generelly apathetic to health issues? The author, a feminist-activist, briefly reviews the sporadic activities concerning women's health and strongly urges that women's health issues should preferably be taken up by women's groups.

All of us have a right to good health. The right to health means not only the right to be free from disease, but also to enjoy physical, mental and emotional well-being. Health cannot be separated from political, cultural or economic systems in which we are living. It cannot be isolated from the roles we are playing and the status we have in society.

My grandmother often used to tell us "Beti, a woman cannot atford sickness. If she does fall sick then she can't complain, but has to bear her illness silently ; for who will tolerate a sick-slave ? ". Many of us have experienced this truth in our own lives or through those of our mothers, grandmothers.

Although it is true that in economically poor classes even the men do not get proper medical aid in sickness, it is the women who are the more neglected group. In fact, even among the economically better off, where it is possible for women to afford good care and proper food, they are found to be weak, or rather not as healthy as they could be. This is because of cultural influences. According to the ideal image of women perpetuated in society, a woman is supposed to be weak and delicate. A 'strong' woman thus becomes, in a sense, the victim of cultural norms. Women are traditionally supposed to eat only after the rest of the family members have eaten and then only what has been left over, even though in poor families it is hardly ever sufficient to keep body and soul together. It will not be an exaggeration to say that she ever gets sufficient rest only on her deathbed.

Menstruation, pregnancy, childbirth, breast-feeding, menopause, all these are considered to be 'women's issues'. In a way society at large has nothing to do with them, because women are not equal members of the society and therefore, complaints about these are treated as, 'psychological' or as 'women's sickness' and are not given the serious consideration they deserve. Doctors and medical professionals produced in this male-dominated society are taught to either close their eyes and ears to such complaints or to immediately connect all women's complaints to their reproductive system. A woman is looked upon as a mere reproductive machine rather than as a human being. Politically also, it is the world-wide phenomenon, that all drives for population control or population increase, breast-feeding or the baby foods campaign have treated women as reproductive machines. Nowhere have these issues been treated in a manner where women's 'health' is given central importance.

In order to understand the location of women's health-issues in the context of feminist movements, it is necessary to broadly define feminism and the feminist movement. Feminism is a new concept in India, a concept not yet well-accepted or understood by the people at large. Broadly speaking one can say that feminism deals with all the aspects of a woman's life and her role in society - - male dominated society. Feminists are interested in changing a hierarchical society and in creating a society where everybody is equal. In today's society, women are at the bottom of the hierarchical structure. In any class, caste or race, whatever their status, women among them are always at the bottom.

No doubt women of the upper classes have more facilities and opportunities than the lower class males, but in their own class they are the least important. Not only that, but because they are women any man from any class can express his superiority as a male member of the patriarchal society. One example is rape.

So the main role of the feminist movement is to unite women to raise their voices against their oppression in a male-dominated society. In her family life, work place, place of education and in all

"Irrespective of educational status, caste or class background, women share the same (health) experience and feelings of inferiority because of their physiology"

the aspects of her life, women have a lower status than men. In our health systems too, the status of women is only as a reproductive machine.

In India, we cannot say that there exists any mass feminist movement. But at the same time it is a fact that there are several women's groups -- feminist groups--who are involved in activities in various areas of women's oppression such as rape, wife-beating, legal reforms and so on. Their activities range from cultural activities to agitational morchas and 'helping' individual women in distress to fight for their rights and the common cause.

But none of these groups have as yet taken health as the prime issue and worked on it. Many of them have touched on one or the other aspect of the issue at some point of time. But there has been no consistency shown regarding the health issues of women. This is because of various reasons which are rooted in our outlook (such as the cultural and social stigma attached to the discussion of women's problems about their bodies.) Many feminists have inhibitions which do not allow them to freely discuss these issues among themselves.

Some groups have made an attempt to raise their voices against oppression through medical systems. For instance, the Women's Centre in Bombay held a meeting with other feminist groups to discuss the effects of "amniocentesis" as a sex-determination test, which gave rise to demands and concerted action in Bombay. Two of these demands were : (1) Amniocentesis facilities should be allowed only in research instituions with proper machinery and control; (2) The government and the medical profession should be brought under pressure to abolish pre-natal sex-determination. It was pointed out that unless and until major social upheaval takes place regarding the status of women in society, female babies will continue to be murdered. *(See article on Amniocentesis.)*

Recently, another meeting was held by the Women's Centre to discuss the issue of Depo-provera, the controversial injectable contraceptive. Womens magazines - feminist ones such as *Baija* (in Marathi) and *Manushi* (in Hindi and English) have given importance to the health and reproductive activity of women by bringing out special issues on the subject. Baija's special issue was on women and health in which the whole proplem had been discussed from the feminist point of view.

Organisations which are working in health such as the People's Science Movement, Medico Friend Circle, (MFC) have also touched on the women's health problems. The Lok Vidnyan Sanghatana, Maharashtra, had prepared an exhibition on women and health which received a tremendous response from various women's groups as well as others working among the toiling masses. This was the first attempt made to discuss the woman's body and her health, reproduction and social biases about it. The exhibition was taken to many villages and it was a thrilling experience to find that women are able to relate to one another while discussing their experiences about their bodies from menstruation to menopause. They were all encouraged by the fact that as women, irrespective of educational status, caste or class background, they have gone through the same experiences and feelings of inferiority because of their physiology. The explanations we had received were shrouded in myth and the actual scientific explanation of the various functions that a woman's body has to perform had been denied us.

The exhibition criticises the social outlook and stigmas attached to the female sex in society and superstitions about women's bodies and child bearing especially with regard to producing male children. Mainly the posters about sex-determination and about fertility, entitled "Who is responsible for not getting a child ?" have made a great impact and have very positively put forward the view that a woman is not wholly, nor mainly responsible. The exhibition emphatically argues that a woman is not merely a reproductive machine. In adivasi areas as well as urban areas like Bombay, Nasik, Pune, Miraj the exhibition attracted large numbers of women.

This exhibition was shown *by* women and *only to* women. It is only in this situation that women can become vocal about their problems. It is very important to realise that women can relate only to other women when it comes to health and their bodies because only women can truly understand one another's problems. I feel very strongly that **women's organisation mainly should handle the issue of women and health, as male activists, although sincerely interested in understanding the problems, are not able to evolve a movement or even a group around the subject.**

"Women's groups should take prime responsibility about women's health issues. Other organisations in health can help in a number of ways....."

At Anand the MFC held an annual meeting in 1983 where many women were called from various groups which were interested in women and health. Majority of the women, who were educated and were working in one or other organisation found it difficult to discuss their problems in the meeting when men were present as even with the desire and sincerity to understand the problems, male participants were unable to understand the intense emotional severity of the problem. At the session where only women were present, there was a live discussion and a free exchange of experiences.

Here I do not intend to devalue the male-activists, who are really helping to raise the voice of women against the medical oppression of women. MFC activists have brought out various articles and debates on the problem. Peoples Science Movement groups have made attempts to make people aware through health exhibitions, the posters and pamphlets on Anaemia. In both the organisations, it is mainly women activists with the help of male activists who have worked very hard for it.

We can conclude that women's organisations should take prime responsibility about the women's health issues, and other organisations in the health area can help them in a number of ways. With this mutual co-operation, one can hope for a strong women's health movement.

The Women's Centre in Bombay is planning to start some health activities. They will be mainly (1) Educational - making women aware of their body and its functions, to help them to tackle the social prejudices and superstitions and to create a healthy outlook about themselves; (2) Preventive ; and (3) Curative - With the help of sympathetic medical proffesionals to help women in preventing and curing health disorders.

Most of us have very little control over the health care system, very little say in the decisions as to what kind of health care is available to us. Women perhaps, are most affected by the health care system or the lack of it. In all phases of our lives, we face difficulties and become the victims of health care system. As potential mothers, as mothers, as housewives, as consumers in order to keep ourselves in accordance with the beauty norms of the society, women are either neglected or misguided by the health care system. To raise our voices against this, women's groups should start (and are actually starting) to organise around health issues. Only this can lead to a strong and united fight against all sorts of oppression in male-dominated society.

Attention SHR Readers !

As you know we have the honour of printing SHR and we hope you like it.

We would like to introduce ourselves as a different kind of business venture : we give special service-attention to socially-oriented individuals, groups and organisations. Besides being reasonably priced we undertake total proof-reading responsibility and help you in designing lay-outs and overall production of material. We also do the posting of publications from Belgaum on your behalf, if desired. All this means a lot of burden off your shoulders and more time for you for more creative work. So, if you have anything in mind for publication, do write to us.

OMEGA PRINTERS, 316 Dr. S. P. Mukherjee Road, Belgaum 590 001 Tel. 24124

Why Don't We Organise

Sir : It is a happy development that a forum for debating and defending a radical perspective on health care has come into existence. If the first issue is any guide I have no doubt that the forum is going to be an instrument of immense value to socialist activism in the health sphere. Wish you all success !

May I share an idea here regarding what I think is an essential requisite for continuity and accountability in this effort. If the persons interested organise themselves into a society (maybe, Indian society for Socialist Health Care - ISSHC) it gives us an identity, a shared cause for loyalty, and, no less important, a firm ground from which to influence, to bargain, and to relate to other organisations, agencies and governments. Further if the society has at least one Annual Conference it will provide us the much needed person-to-person interaction for enhancing enthusiasm and exchanging ideas.

I would suggest two streams of membership :

Members—All persons qualified and directly engaged in health care, irrespective of their position in the health personnel hierarchy. This includes health visitors, nurses, auxiliary health workers, dentists, pharmacists, physicians, surgeons etc. The other stream of membership will be that of *Associate Members* for all those interested in socialist health care but not directly engaged in health care. This includes teachers, lawyers, politicians, engineers etc., practically anybody from the public.

Dr. N. Janakiramaiah

Asst. Professor of Psychiatry, National Institute of Mental Health & Neuro Sciences, Bangalore 560029

WORKING EDITOR'S REPLY : We share your viewpoint that radical activists working in the field of health or interested in it, need person-to-person interaction for enhancing enthusiasm and exchanging ideas.

But we feel that it would be a terrible mistake to form a separate organisation of socialists interested in health issues. That will be the best way to isolate socialists from the wider movement on health issues. In fact, not marxists but other radicals were the people who gave meaning to radical medical practice while some socialists have only very recently started questioning the official communist view of health i.e. (i) merely more equitable distribution of medical care and (ii) the content of medicine and medical practice as being value free. Therefore no comprehensive marxist understanding of health and health care exists. Genuine (undogmatic and scientific) marxist theory and practice in health can develop only as an outcome of our interaction and work with wider stratas of radical activists.

Fortunately in India, a broad radical thought current does exist — the Medico Friend Circle, and many of us are part of it. Many of us have been and are, actively involved in its activities including its journal the MFC bulletin. The idea of a journal like SHR came from these MFC members not with a sectarian motivation of providing any 'alternative' to the MFC and its bulletin, but to help focus and sharpen the debate amongst the radicals working in health and in turn, widen the basis of radical medical work and of marxist political praxis.

The MFC is a decade old and has helped to radicalise many health workers. We feel it is still relevant and all radical activists experiencing a need for such organisation should join the MFC and be part of the process of radicalisation started by it.

Protest Against Marxist Male Chauvinism

Dear comrades : I am writing to lodge a strong protest against Dhruv Mankad's reference to our joint article (Health Care in a Revolutionary Framework : Possibilities for an Alternative Praxis, SHR 11) as 'Binayak Sen's article' in his editorial perspective (page 3, SHR 1 : 1). *(Contd. on page 71)*

MANUSHI

A Journal About Women And Society
Brought out by a group of women in New Delhi

More Than A Magazine – A Cause

Brings you

- Investigative Reports on women's situation in different parts of the subcontinent, among different communities castes, classes
- News about women's organised struggles
- Interviews, lifesketches
- Film reviews
- Women in history
- Fiction, poetry, artwork
- Letters from readers
- And much more

AMNIOCENTESIS AND FEMALE FOETICIDE
Misuse of Medical Technology

vibhuti patel

Murder of the female child is not new in India. This practice still continues, only the methods of committing such murder have changed. Such practices reflect society's attitude towards the female sex. The patriarchal male-dominated system has evolved modern methods to perpetuate women's oppression in today's socio-economic system. The author analyses the reasons for the popularity of one such modern medical method, amniocentesis, as a pre-natal sex determination test and argues that it is meant to exterminate women and perpetuate their oppression, she also emphasises the need to fight sexist abuse of this medical technique.

Amniocentesis, a scientific technique that was supposed to be used mainly to detect genetic deformities has become very popular in India for detection of the sex of a foetus. For that 15-20 ml of amniotic fluid is taken from the womb by pricking foetus membrane with the help of a special kind of needle. After seperating foetal cell from the amniotic fluid, a chromosomal analysis is conducted on it. This test helps in detecting several genetic disorders like mongolism, defects of neurotube in the foetus, retarded muscular growth, 'Rh' incompatibility, haemophilia and other types of abnormal babies. This test should be conducted on women above 40 years because there are higher chances of mongoloid children produced by such women. In some cases, a sex determination test is required to identify sex-specific deformities such as haemophilia, retarded muscular growth which mainly affect males.

Limitations of Amniocentesis

This test can give 95-97% accurate results. Thus it is not totally reliable. In Harkisandas Hospital and Pearl Centre, Bombay, where this test is conducted on thousands of women, it was noted that the test had affected foetus adversely to 1% of the total number of cases. Thus the test may lead to spontaneous abortions or premature delivery, dislocation of the hips, respiratory complications, needle puncture marks on the baby (Chhachhi & Sathyamala, 1983).

The test is conducted after completion of 16 weeks of pregnancy and within a week the findings are available. In our country, the facility of amniocentesis is available only in big cities like Bombay, Delhi, Chandigarh etc., hence patients from villages and small towns get the results by post; that takes one more week. By the time they decide to abort the foetus, it is over 18 weeks old. Abortion at such a late stage is quite harmful for the mother.

Popularity of the Test

The amniocentesis tests became popular in the last three years though earlier they were conducted in the government hospitals on an experimental basis. Now these tests are conducted for sex determination and thereafter extermination of female foetus through abortions, in private clinics and hospitals and government hospitals in many cities of India like Bombay, Delhi, Amritsar, Chandigarh, Baroda, Ahmedabad, Kanpur, Meerut etc. This perverse use of modern technology is encouraged and boosted by money-minded private practitioners who are out to make a woman, "a male-child-producing machine". As per the most conservative estimate made by a research team of Women's Centre, Bombay, based on their survey of six hospitals and clinics, in Bombay alone 10 women per day undergo test. This survey also revealed the hypocrisy of "non-violent", "vegetarian", "anti-abortion" management of the city's reputed hospital - Harkisandas Hospital, that conducts ante-natal sex-determination test. Their handout declares the test as "humane and beneficial". The hospital has out-patient facilities and there is such a great rush for the test that one has to book one month in advance. As the management does not support abortion, they recommend women to various other hospitals and clinics and ask them to bring back the female foetuses after abortion to them for further "RESEARCH". (Abraham & Sonal, 1983).

In other countries, this test is very expensive and is under strict governmental control, while in our country this test can be done at between Rs. 80 to Rs. 500. Hence not only upper class people, but even working class people can easily avail this facility. A survey of several slums in Bombay showed that many women had undergone the test and after knowing that the sex of foetus was female, had undergone abortion in the 18th or 19th week of pregnancy. Their argument was it is better to spend Rs. 80 or even Rs 800 now than give birth to a female baby and spend thousands of rupees for her marriage when she grows up.

Controversy Around Amniocentesis

Three years back a controversy around Amniocentesis started as a result of several investigative

reports published in popular magazines like *India Today, Eve's Weekly, Sunday* and other regional -language journals. One estimate that shocked everyone, right from planners and policy-makers to the academicians and activists was : Between 1978 and 1983, around 78000 female foetuses were aborted after sex determination test in our country. (TOI June, 1982).

The government and private practitioners involved in this lucrative trade, justify the sex determination test as measure for population control. Women have always been worst target for family planning policies. Harmful effects of pregnancy test, contraceptive pills, anti-pregnancy injections, camps for mass-sterilisation of women with their unhygenic atmosphere are always overlooked by the enthusiasts of family planning policy. Most of population control research is conducted on women without giving any consideration to the harm caused by the research to the women concerned. Advocates for population control will continue cashing in on socio-cultural values that treat the birth of a daughter in the family as a great calamity and perpetuate modern method of massacaring female foetuses on a massive scale.

India has a legacy of killing female children *(dudhapiti)* by putting opium on the mother's nipple or by putting the afterbirth over the child's face or by illtreating daughters. (Clark, 1983). These days also female members of the family get inferior treatment as far as food, medication and education is concerned (Research unit on Women's Studies, 1981). When they grow up, there is further harassment for dowry. "Then, is it not desirable that she dies rather than be illtreated?" ask many social scientists. In Dharma Kumar's (EPW, June, 1983) words : "Is it really better to be born and 'left to die' than to be killed as foetus? Does the birth of lakhs or even millions of unwanted girls improve the status of women?".

But what can be the long-term implications if such a trend continues ? Will it not aggravate the already disturbed sex-ratio ? There has been continuous decline in female/male sex-ratio between 1901 and 1971. Between 1971 and 1981 there was slight increase, but it still continues to be adverse for women.

Demographic Profile of India (in millions) 1901-1981

Year	Total Population	Male - Population	Female - Population	Total No. of women per 1000 men i e. sex ratio.
1901	238	121	117	972
1911	252	128	124	964
1921	251	128	123	955
1931	279	143	136	950
1941	319	164	155	945
1951	361	186	175	946
1961	439	226	213	941
1971	548	284	264	930
1981	684	353	331	935

Source : *Census Report,* 1981, Series 1, Paper 1.

Here too, economists have their reply ready i.e. law of demand and supply. If supply of women is reduce, their status will be enhanced. Scarcity of women will increase their value (Bardhan, 1982). According to this logic, women will not be burnt alive because of dowry problem as they will not be easily replaceable commodity. But here the economists forget the socio-cultural milieu in which women have to live. The society that treats a woman as a mere sex-object will not treat women in a more 'humane' way if they are scarce in supply. On the contrary there will be increased incidences of rape, abduction and forced polyandry. In U. P, Haryana, Rajasthan and Punjab among certain communities, sex-ratio is extremely adverse for women. There a wife is shared by 'a set of brothers' (or some times even by patrilateral parallel cousins) (Dube, 1983).

To think that it is better to kill female foetuses than giving birth to unwanted female children, is very fatalistic. By this logic it is better to kill the poor rather than let them suffer poverty and deprivation. How horrifying !

Another argument is that in cases where women have one or more daughters, they should be allowed to have amniocentesis done so that they can plan a 'balanced family' by having sons. Instead of going on producing female children in the hope of getting a male child, it is better for the family's and the country's welfare that they abort the female foetus and have small and balanced families with daughters and sons. This concept of 'balanced family' also has a sexist bias. Would a couple with one or more sons undergo amniocentesis to get rid of male foetus and have a daughter for balancing their family ? No, never !

This frenzy of having a 'balanced family' ! At what cost ? How many abortions (between 16 to 18 weeks) can a woman bear without jeopardising her health ?

Time and again it is stated that women themselves enthusiastically go for the test out of their free will. It is a question of women's own choice. But are these choices made in a social vaccum ? These women are socially conditioned to accept that unless they produce one or more male child they have no social worth. They can be harassed, taunted, even deserted by their husbands and in-laws if they fail to do so. Thus their 'choices' depend on

the fear of society. It is true that feminists all over the world have always demanded "the right of women to control their own bodies/fertility and choose whether or not to have child/children and have facilities for free, legal and safer abortions." While understanding these issues in the third world context we must see it in the background of the role of imperialism and racism that aims at the control of "coloured populations". Thus : "It is all too easy for population control advocates to heartily endorse women's rights at the same time diverting attention from the real causes of the population problem. Lack of food, economic security, clean drinking water and safe clinical facilities, have led to a situation where a woman has to have 6.2 children to have at least one surviving male child. These are the roots of the population problem, not merely the 'desire to have a male child'" (Chhachhi, and Sathyamala, 1983).

Meetings called by Women's Centre (Bombay) and various women's organisations in Delhi, discussed this problem at length and three positions emerged. 1. Total ban on amniocentesis tests; 2. Support to amniocentesis tests; and 3. Amniocentesis tests to be allowed under strict governmental control and only for detecting genetic abnormalities.

Most of the women's organisations feel that the 3rd position is most advantageous even if one accepts the fact that illegally, the tests will be conducted by unscrupulous people. To avoid this, women's organisations and other socially conscious groups will have to act as watch dogs.

The issue of amniocentesis once again shatters the myth of neutrality of science and technology. Hence, the necessity of linking science technology with socio-economic and cultural reality. Class, racist and sexist biases of the ruling elites have crossed all boundaries of human dignity and decency by making savage use of science. Even in China after 10 years of 'cultural revolution' and 'socialist thinking' sex determination test for female extermination are largely prevalent after the government's campaign for one-child-family began (Sunday, 1983). Chinese couples willy-nilly accept a system of one-child-family but the child has to be a male. This shows how adaptive the system of patriarchy, male supremacy is. It can establish and strengthen its roots in all kinds of social structures, pre-capitalist and even post-capitalists, if not challenged consistently.

(Contd. from page 68)

I am unable to understand the thought process behind the omission of my name. Does Dhruv Mankad assume that because I am married to Binayak Sen, my contribution to a joint production is subsistence (= negligible = zero) ? I would be grateful if he could clarify what lies behind this e.g. of marxist male chauvinism - for we can only begin to advance towards correct action from correct analysis.

May I congratulate you on an excellently produced first issue ?

Ilina Sen
Dalli Rajhara

DHRUV MANKAD REPLIES :

I tender my sincere apology to Ilina Sen for not mentioning her name in the editorial perspective while referring to a joint article by her and Binayak Sen. The error occurred due to the fact that before writing the perspective, I had not seen the actual article referred to above. I knew about the contents only from discussions with Binayak at Calcutta and later with Anant Phadke, Manisha Gupte Awasthi, Padma Prakash, Amar Jesani at Pune. Till I saw the article in print in SHR, I was under the honest impression that it was indeed written by Binayak only. This is what lies behind " this e.g. of Marxist Male chauvinism".

Despite this apology, I do wish to state that Ilina Sen's 'protest' is petty and unprincipled. She has thrown wild allegations 'of Marxist male chauvinism' on my part without first giving me a chance to explain. This kind of immature reasoning based on mere presumptions - that too, incorrect ones, would lead us neither to correct analysis nor to correct action but only to bickerings and quarrels.

I am restraining myself in my reply with the intention not to extend this issue any further. I hope in future, such errors are avoided and if and when they do occur the reactions thereto are more responsible.

WORKING EDITORS' REPLY : The omission was our fault rather than Dhruv's, because we were responsible for checking the final proofs and were of course aware of the joint authorship We regret the inadvertant slip

RURAL ENERGY SITUATION
Consequences for Women's Health

srilatha batliwala

This article examines the interrelationship between women's work, the growing scarcity of energy resources for survival, and its impact on women's health and nutrition. Women contribute 53 per cent of the human energy required for survival tasks. And yet they eat far less than they require. Women's calorific intake is about 100 calories (per woman per day) less than they expend whereas men show an 800-calorie intake surplus. The article raises some very important questions with regard to women's work, their food intake, access to health care and women's morbidity patterns and examines the energy - health - nutrition syndrone. This is based on a paper presented at the Conference on 'Women and Poverty' in Calcutta, 1983.

Dorland's Medical Dictionary defines the word syndrome as "a combination of symptoms result-from a single cause or so commonly occurring together as to constitute a distinct . . . . . entity". It is hard to find a more apt definition of energy, health and nutrition and their relationship to poverty.

It may be felt that poverty has an impact on the health and nutrition of all the poor, regardless of age and sex. Is there something unique about its impact on women ? Or inversely, do women bear an additional burden - in terms of their health, nutrition, or anything else - in a poverty situation ? This paper attempts to show that they do - and also why strategies for women's health and nutrition need to be emphasised within strategies for general development.

In the field of nutrition, most strategies have been aimed at increasing food intake indirectly or directly (Natarajan, 1974; and NIPCD, 1976: Batliwala, 1978). Women are targets of the latter programmes only during pregnancy and lactation. On the other hand, there has been little or no study of the possible effects of reducing energy expenditure - or to put it simply, reducing the overwhelming drudgery of the poor, and especially of poor women. This is not proposed as an alternative to raising food intake, but as an additional (and possibly critical) facet of improving women's nutrition and health. Such energy saving, as we shall see, is not only a nutritional asset but may also release a significant amount of women's time.

The greater work load on women has been observed for centuries and rather embarassedly reduced to a sheephish joke by men. But until recently, there was no detailed study of the relative work outputs of women and the nature of such work. In 1981, however, the Application of Science and Technology to Rural Areas (ASTRA) (a cell of the Indian Institute of Science, Bangalore) published the report of their three-year field study of rural energy consumption patterns (ASTRA, 1981). The study was conducted in rural Karnataka with a sample of six villages comprising 560 households and a population of 3,452.

One of the most significant results of ASTRA's study, was the role of human energy - and specifically women's energy - in the rural energy matrix. Table 1 summarises the findings :

Table 1 : Pattern of Village Energy Supply & Consumption

Source-wise contribution		Sector-wise consumption	
Source	Per cent	Activity	Per cent
Human	7.7	Agriculture	4.3
(Men)	(3.1)	Domestic	88.3
(Women)	(3.8)	Lighting	2.2
(Children)	(0.8)	Transport	0.5
Animal	2.7	Industry	4.7
Firewood	81.6		
Kerosene	2.1		
Electricity	0.6		
Other	5.3		

Source : ASTRA, 1981, "Rural Energy Consumption Patterns - A Field Study", Bangalore, Indian Institute of Science, p. 80.

If we exclude firewood, we find that human beings were the most significant energy contributors - even more than animals. Moreover, if we disaggregate human energy, men, women and children contribute 31%, 53% and 16% of human energy, respectively. The ASTRA study also showed that most human energy was spent not so much on economically productive activities but on survival tasks such as gathering firewood, fetching water, and cooking.

What is the role of women in these activities, and what is the magnitude of the burden on them

Table 2 :

Time and calorie expenditure on domestic and agricultural activities and their calorie cost (for man, woman and child)

Activity	I Hours/day M	W	C	II Calorie cost (cals/minute) M	W	C	III Calorie/day M	W	C

Col. I : Source : Compiled from data given in ASTRA, 1981 : *Rural Energy Consumption Patterns : A Field Study* Indian Institute of Science, Bangalore.

Col. II : *All estimated or approximated figures.

(i) N. L. Ramanathan and P. G. Nag, : *Energy Cost of Human Labour*, National Institute of Occupational Health, Ahmedabad.

(ii) R. Rajalakshmi, 1974 : *Applied Nutrition* (Second Edition), Oxford and IBH, New Delhi

compared to that on men? To determine this, we have to examine the hours per day spent on domestic and agricultural activities and translate these into calorie costs. Table 2 (col I) present the break-up of hours per day spent on agricultural and domestic activities by men and women.

The most significant aspect of Table 2 (col. I) is that while women average about 6 hours a day on survival-related and agricultural tasks, men average only 4 hours a day on the same. Also, the ASTRA study did not monitor **other** domestic work such as cleaning, sweeping, washing of clothes and utensils and child care, all of which are calorie-intensive and all of which are performed almost exclusively by women. On the other hand, most of the other (i. e., non-enumerated) tasks carried out by men are sedentary in nature - such as visiting the tea shop, trips to panchayat offices, talking with friends, and so on.

We have now to translate the activities of men and women into calorie costs and compare them with calorie intake. However, this is not as simple as it seems for once again **the neglect of women in social research or the ideological biases within existing information systems becomes a handicap.**

Ramanathan and Nag have reviewed virtually all calorie cost studies in the country for various activities in their paper *Energy Cost of Human Labour.* They found energy cost estimates for only 10 agricultural activities, compared to 70 industrial and military activities. Furtherrnore, there were no female equivalents for these agricultural tasks, as though women have not been participating in agriculture for several millenia !

The unkindest cut of all is when we find that the few women's energy costs (10, to be precise) which have been measured are clubbed under the category of 'sedentary people' and include such pleasant tasks as sewing, knitting, typewriting, piano-playing and singing. Where have 90% of India's women gone - the ones who work from morning to night at back-breaking domestic and economic tasks and also carry the burden of pregnancy and child care?

Under the circumstances one is forced to approximate the energy expenditure of women in the concerned tasks by using the fomula :

$$\frac{\text{energy cost/minute/adult male} \times \text{Basal Metabolic Rate female}}{\text{Basal Metabolic Rate male}}$$

(the BMR for moderate workers is used throughout the formula)

This gives us the estimates of energy cost per minute per activity for men and women presented in Table 2 (col II). Please note that all starred figures are estimates based on the above formula.

We are now ready to calculate the activity-wise energy output per day for man and woman, shown in Table 2 (col III).

A note of explanation in needed here : Agricultural activities are obviously seasonal but here they have been averaged over the whole year to obtain a daily figure, which is more appropriate for determining daily energy output and comparing it with calorie intake. Thus, during some months of the year, agricultural activities will account for much higher energy expenditure than shown in Table 2 (col. III)

We see that the calorie (energy) expenditure of women is higher than that of men. The difference appears more marginal than I suspect it really is. First of all, the 'other' activities of men, could not be clearly enumerated.

The shortage of off-season employment opportunities makes it doubtful that they spend a lot of energy in non-agricultural activities. Therefore one can postulate that during off-seasons the total calorie expenditure of men may be significantly lower than that of women.

Secondly, we see that most of the energy expenditure of women is on daily, life-supporting tasks which must be performed regardless of season and which are generally not shared by men - viz, cooking, fetching water, gathering firewood, washing, cleaning, and child care.

Thirdly, many of the above activities create a demand for human energy because of the scarcity of other energy resources. If cooking fuel and water were readily available close to the user and the efficiency of stoves improved, a saving of nearly 500 calories per day per woman could be effected. Is there a need to bring about such an energy saving at all ? If food intake more or less matches calorie output, there would appear to be no cause for concern. ASTRA's nutrition survey (unpublished) in the village Ungra (based on monitoring of food purchase and use over a two-month period) found that the average individual intake per day was around 2300 calories.

But this, like all other nutrition surveys in the country, assumes an equal distribution of food within the family - a highly questionable assumption.

The staple diet in this area is 'ragi' which is cooked to a dough and separated into balls for eating. When local women were questioned as to how they distribute the balls, their answers provided the following ratio : 2 balls for a man, 1.5 for a woman and 1 for a child. Obviously this would be a questionable basis for disaggregating the overall calorie consumption of the family - but it gives us a rough idea of intra-familial inequalities in food distribution. It also shows that food intake is determined not only by work output, but also by social and cultural factors which have to be studied, described and tackled.

Let us for a moment, return to the above ratio and assume it is valid. Applying it to the overall cereal consumption per day per family (4.24 kg) the relative food intake per man, woman and child would then be 3270 calories, 2410 calories and 1640 calories per day respectively. **This means an intake deficit of nearly 100 calories per day per woman, whereas a man has an intake surplus of nearly 800 calories.**

A deficit of 100 calories a day doesn't look serious until we link it to other facts : (i) The vast majority of the population have worm infestations, and these parasites can 'steal' as much as one-fourth of the total food intake. (ii) This intake level for women is a 'maintenance' level which makes no allowances for the additional 500-600 calories required during pregnancy and lactation - and Kamala Jaya Rao (1980) has shown that one-third adult Indian women are in that condition at any point in time, without the benefit of additional nutrition during these 'vulnerable' periods.

All of the nutrition programmes in the country are aimed at pregnant and lactating women - though how much of this extra nutrition actually reaches these women is a moot point (Natarajan, 1974). But what of the nutrition deprivation suffered by girls from infancy to pregnancy? And what of the women who have fulfilled their reproductive roles, but must continue to work for their family's survival without enough food to meet their needs?

Health hazards of cooking stoves and fuels

Beyond the nutrition factor there are other ways in which the village energy system affects women's health. Domestic fuel scarcity is only one part of the crisis women face. **Having obtained some form of fuel**, poor women are forced to cook on stoves which are both primitive and inefficient. The traditional chula, used in the vast majority of Indian homes, ranges from a crude pit or U-shaped pile of bricks to the more sophisticated fired clay or metal stove. The cooking efficiency of these stoves is dismally poor : between 3 and 10% (Geller, 1980). Since the fuel efficiency of a stove determines not only fuel consumption (and hence fuel-gathering time) but also the length of time spent in cooking, the traditional chula condemns women to spend at least 3 hours a day on cooking, and that too for most of their lives!

As if this were not a severe enough penalty, some recent studies have highlighted the extreme health hazards to women and girls where conventional bio-mass fuels like firewood, cowdung and crop wastes are used as cooking fuels (SNDT, 1983).

Dr. Kirk Smith, energy programme chief of the Resource Systems Institute of East-West Central Honolulu, conducted a study in rural Gujarat in association with the National Institute of Occupational Health (Ahmedabad) and the Jyoti Solar Energy Institute (Baroda). The study was conducted in 4 villages of the Kaira District. Smith's team found that traditional bio-mass fuels emit more Toxic Suspended Particulates, (TSP) benzo-a-pyrene, carbon monoxide and polycyclie organic pollutants than fossil fuels. Thanks to the crudity of stoves and the poor ventilation of the rural home, these fuel emissions produce a deadly disease trap for women and girls - for the study found that the women begin regular cooking at around 13 years of age (Indian Express, 1983).

Clinical studies by the Kirk Smith team found that women spending around 3 hours a day on cooking were exposed to 700 microgrammes of particulate matter per cubic metre, compared to the safety level of 75 microgrammes. The benzo-a-pyrene inhaled alone was equivalent to smoking 20 packets of cigarettes a day. (SNDT, 1983)

In another study conducted by the Jawaharlal Institute of Postgraduate Medical Education and Research (JIPMER), 20 albino rats were exposed to cow dung smoke and soon developed chronic bronchitis, bronchiolitis and emphysema. The JIPMER Study suggested this as a possible cause of the high incidence of bronchinal disease among women and older girls in India (Indian Express 1983). In light of these facts, it is not surprising that respiratory disease is one of the major causes of death among women in India (SNDT, 1983).

One of the solutions developed to combat this problem is the 'smokeless' chula. The 'Nada' chula and 'Dholadhar' chula, among others, are some of the most sucessful designs. Designers and disseminators have reported not only fuel savings of 50% with these chulas, (IGDP, 1982) but the remarkable changes they have wrought in the lives of women and children; the fuel saving has released precious time which has been used in a variety of ways, including, as one woman put it, to "just lie down and rest" (Sarin, 1983).

Unfortunately, women's ill-health and undernutrition is not of equal concern to all. There is a growing school of thought which uses theories of biological adaptation (the 'homeostasis' theory) and clever statistical gymnastics to prove that there is in fact no such calorie gap (Sukhatme, 1981).

The doyen of this school is Prof. P.V. Sukhatme, a biostatistician with considerable clout who, a decade ago smashed the theory of the 'protein gap' in the diets of poor people. He demonstrated that the protein gap only occurs when there is a *calorie* gap - but when overall intake of calories is sufficient, the amount of protein is also adequate (Sukhatme, 1972). He was undoubtedly responsible for elbowing out the vested interests who would have liked to manufacture and market supplementary protein to people who had barely enough to eat.

Today his work has taken quite a different direction - a direction which has frightful implications for women. To grossly oversimplify his theory, he states that just as there is inter-individual variation in food intake, there is also an intra-individual variation. So at times we eat more, and then we eat less. Thus, ascribing some arbitrary norm such as 'recommended daily allowance' is meaningless, since both inter- and intra-individual food intakes will fall into a normal bell curve, with the majority of people in the centre and a few at either extreme, even though everyone is healthy (Sukhatme, 1981). From here, he goes on to state, that the only two indicators of malnutrition (either in the form of overnutrition or undernutrition) are : whether body weight remains basically constant (i. e., it is 'maintained'), and whether the normal level of activity (for which read 'work') is maintained. He believes that anyone who meets the above criteria cannot be termed malnourished.

Sukhatme also does not want us to be carried away by Western norms of how tall or heavy we should be. A thin, small person is neither stunted nor underwight - she/he has merely 'adapted' to efficiently use the little food to be had while continuing to labour away for survival.

Therefore, this 'calorie-gap' suffered by women and by many of the poor is of little consequences because they 'adapt' themselves and carry on. A comfortable theory indeed ! Women, in fact, are the stumbling block in Sukhatme's theory. Can women 'adapt' to calorie deficits of 500 or 600 calories during pregnancy and lactation ?

Even if they can, Sukhatme ignores the possibility that such adaptation over a lifetime may have disastrous consequences on health. Is this why more women die, and die earlier than men ? (HFA, 1981) Is this why maternal mortality is so high - 400/100,000 ? Is this why the average birth-weight of poor babies is as low as 2.5 kg (NIN, 1971), leading to so much child wastage ? In other words this may be the starting point of the vicious circle of maternal undernutrition, low birth-weight babies, high infant mortality and high fertility. In this context, health care services can play an important role in alleviating the health problems of women to some extent - but do they?

First of all, women's health has been confused with maternal health — once again on the assumption that women and maternity are one and the same thing. The only women-oriented programmes in the national health sector have been Maternal and Child Health Schemes and to some extent Family Planning. The health system has yet to waken to the fact that there are a large number of women in need of health care who are neither pregnant nor lactating.

Secondly, the outreach of health services is very poor with respect to women. Examination of in-and-out-patient records of medical institutions reveals that for every three men who avail of these facilities only one woman does so. This is by no means because women are healthier, but because in the Indian family, the importance given to a woman's ailments is considrably less than that given to a man's illness.

Thirdly, the very nature and structure of the health service system mitigates against its reaching women. Our health system is institution-based. Women have neither the time, mobility, child care facilities nor the leisure to travel long distances at great expense to seek out the services available in hospitals and health centres, often at the loss of a day's wage. A domiciliary system which reaches the doorstep would automatically benefit more women than today's set-up.

Finally in our culture, it is women who can best reach out to and care for other women. Yet in the present health services, male functionaries heavily outweigh the females. Although the number of women doctors has been steadily rising, few of these are working in the rural areas. It is the lone cadre of Auxiliary-Nurse-Midwives, poorly paid, poorly supervised and equipped, sexually harassed and overloaded with work, who are the sole guardians of women's health. Even the celebrated Community Health Worker Scheme, defeated our hopes when over 80% of those selected and trained turned out to be men.

Conclusions

The scarcity of other energy resources in a rural area creates a demand for human energy - particularly in survival-related tasks. When human energy is expended, women contribute the greatest share. But in comparison to this energy output, women get a lower share of food intake, and face a nutritional deficit. Added to the work burden, women also suffer further energy deprivation due to repeated pregnancies and breast feeding, high morbidity and intestinal infestations. Health care can alleviate this burden to some extent, but women apparently have less access to health care facilities due to the nature and structure of these services. These factors naturally affect all the poor, but women are more seriously affected because of their low status, and their social and economic roles.

I cannot presume to offer solutions—the complexity of the problem is mind-boggling. But I can and do raise a series of questions which must be answered if we are to even begin tackling the problem. The questions are :

(1) What is the actual pattern of women's work in different regions?

(2) What is the energy cost of the activities performed by men, women and children in different socio-economic groups - both urban and rural?

(3) What are the effects of human energy saving on nutrition status - with and without increasing food intake?

(4) Are the calorie intake norms or recommended daily allowances for women at various activity levels realistic?

(5) What is the actual food intake of women (at all ages and biological stages) and men ?

(6) How do women utilise the time released by the provision of alternative energy resources for survival tasks ?

(7) What is the actual extent and pattern of morbidity amongst women ?

(8) What is the outreach of health services to all women, and what is the level of utilisation of the former by the latter ?

In conclusion, and although I have said I can offer no solutions, the interrelationship between energy scarcity, women's work, nutrition and health suggests a three-pronged strategy :

Women's deprivation is occurring at three levels: the socio-cultural level, the environmental level and the service-programme level. The erosion of rigid patriarchal system has to occur, and all women's movements are aiming at this. Improving the availability of energy resources with priority for the activities performed by women (collecting fuel and water, cooking, and so on) is another facet of the strategy, and one where alternative technology can play an important part. Finally, there is an urgent need to restructure and expand the scope of existing programmes to reach out to women and draw them into the health care network.

How best all this can be achieved is a matter for further debate and discussion. But it is clear that the major thrust has to be on the political front, by mobilising women to analyse their situation and articulate their demands.

HEALTH OF WOMEN IN THE 'HEALTH' INDUSTRY

sujata gotoskar, rohini banaji and vijay kanhere

The authors of this article provide a new dimension to all those working for rational drug policy, against misuse of drugs, and so on Individuals and groups working in health have so far formulated their programmes with a concern for the consumers of drugs. But an important section, the producers of these drugs is left out. The authors' study of health problems of women workers in the drug industry shows that they are the first and worst sufferers. They stress the need for health groups to orient themselves towards producers of drugs, as workers need their expertise, and to find a strong and reliable ally in their fight against the controllers of drug industry. Health groups, trade unions and women's groups have many meeting points.

In the last two decades, some amount of thought, research and action has gone into the health hazards posed by the drug industry vis-a-vis the consumers of the products. Voluntary health groups and agencies are exposing the dangerous effects of drugs taken in quantities of 5 milligrams a day over years or also just once. However, hardly has any concern been directed against the effects of these drugs on the producers, the people working in the companies producing these drugs. The workers in their work process are exposed to the same drug, inhale the same drug, the drug enters their systems thorugh touch, through the mouth and through their respiration. They work for 9 hours a day, day after day, year after year, producing hormones, vasodilators, antibiotics etc.

If one has to look at the drug industry from the point of view of the health effects on the producers, one cannot be confined to a narrow conception of health as a lack of disease initiated by a drug. The conception of health effects has to be broadened considerably.

Drug Production and Worker's Health

The last ten years have seen a phenomenal increase in the production of Bombay pharmaceutical companies and in that of newer industrial centres. Many more liquid orals, tablets, vials, ampoules have been thrown in to the market. This is leading, not to increase in employment, but to the extraction of more work from less or the same number of workers. The impact of this process is increasingly being felt by the women on the packing lines. Behind the heavy advertising campaigns stand overworked packers lifting heavy ampoule-rings or heavy crates of bottles. This fantastic increase in production, from 22,000 ampoules per shift to 60,000 ampoules in 7 years or 8,000 to 50,000 per shift in 11 years, with very little increase in the number of women doing the work, is brought about in two ways. These two related methods produce two types of health hazards.

The simplest, age-old but out-dated method is to keep the process intact and increase the speed of the machine and hence of the entire process Such *speed-ups* on manually operated packing lines lead to fatigue, weakness, back-aches, aching arms, feet and shoulders.

Work on the packing line involves the fitting of bottles, sealing, labelling, optical checking, packing in boxes, inserting leaflets and case-packing. All these jobs may be manually done or some jobs are semi-automatic or automatic. The manual filling of bottles is extremely strenuous involving holding the bottles with hands, regulating the volume of the liquid by turning a tap or switch on and off, by pressing a foot pedal to start and stop the flow while holding the bottle under the nozzle. The strain is felt most on the arm and feet muscles.

In the manual spooling of adhesives, the operator mounts the rolls of plaster on the machine and pulls by hand till the plaster reaches the spool. "We have to stand on one foot and to pedal with the other to spool, and at the same time guide the plaster, and finally cut it when the required length has been reached. If the roll is tight, continuous pulling by hand is very strenuous. Continual cutting results in corns. Carrying rolls causes chest pains".

All these operations, when manually done cause extreme fatigue. "We have to lift the heavy rings of the capsule machine several times in the shift. It is very exhausting and dangerous as we have to stand on a stool to fit the heavy rings." By itself the single operation may not be very heavy, but repeated over hundreds of times in the 8 hours of shift, everyday, it becomes strenuous and causes tiredness.

Another major health hazard is the **deteriorating eyesight** of the women working on **optical checking**. Every vial, bottle has to be checked for the presence of foreign particles. Manual optical checking involves the packing up of one or more bottles or vials (depending on their size and weight), shaking

and viewing them against a strong light, sometimes against black and white backgrounds in succession. These have to be checked by the naked eye. Some women optical checkers told us, "Before we came to work here, most of us didn't have to wear spectacles. Now almost all of us have glasses. Sometimes we have to get our glasses renewed every 6 months."

In semi-automatic optical checking, "the bottles pass on a belt in front of the checker with a strong light shining through them. The speed of the belt is high and we cannot shift our eyes at all". "On our line, production increased from 8,000 to 50,000 per shift in 11 years due to the introduction of automatic filling and labelling machines. The optical checkers have increased from 2 to only 4".

Complaints of eye strain in optical checking were most widespread in companies where the women would have to check liquids for one day or more before moving on to another job. Rotation in jobs is an accepted practice in many of the larger pharmaceutical companies. Different types of rotation schemes exist. All the women who work in sections where jobs are rotated said they liked rotation, for two main reasons: (i) "There are hard jobs and easy jobs and the same people shouldn't always have to do the hard jobs". (ii) "It is boring to do the same job all the time".

Where the workers have complaints of fatigue or tedium and want rotation they could, through their unions, try to devise schemes with (a) rapid rotation, perhaps within lines to prevent strain and fatigue in certain operations, and (b) rotations on a longer cycle, such as three months perhaps between lines, to allow workers to become competent at a variety of operations.

The operations which were earlier either manual or semi-automatic and which have now been automated, almost always involve a reduction in the physical effort required to do the work. However, with automation, managements have tried to combine, two or three operations and a single operator has now to cope with 2 or more machines. Though the quantum of physical effort has been reduced, the strain of minding these machines increases manifold and results in mental strain and tedium

Where physical strenous functions have been automated the women often told us that the work had become less tiring. Increases in the level of automation have brought about this result by eliminating certain highly repetitive tasks such as holding bottles or vials under a nozzle, pressing a lever foot-pedal etc.

Any method which replaces the hazardous physically strenous and fatiguing work, by work that is lighter, safer and less unpleasant, and does it in far less time, is potentially a means of emancipation from long working hours, industrial fatigue, coercive work routines, health hazards and rigid sex stereotyping. Whether automation ever has this meaning, will depend on (i) the way in which it is introduced, which depends on (ii) how much control unions exercise over its introduction and use.

Experience of workers demonstrates that if the changes are made completely under management control, the chances are that workloads will increase, employment will decline, health hazards will increase and workers lose any sense of stability in their jobs. **It is only when those who actually work on the machines in the factories have some control over this process through their representatives and unions can the potentiailities of automation be realised.**

When production is increased in such proportions, not only is there an increase in workloads and fatigue for the women workers, but it also results in making the women workers less resistant to the effects of the drug they are producing. At the same time, the possibility of the hazards is multiplied due to the sheer increase in the amount of chemicals the workers come into contact, as in the case of optical checking, the eye-strain increases as the number of bottles and the speed with which they are to be checked increases. The increase in workloads or speedups is hazardous in itself and it also increases the intensity of the hazardous effects of the chemicals.

Health Costs of 'life saving' Drugs

Here we will go into the *case-study* of one such product-Isosorbide dinitrate. This is used as a coronary vasodilator for the treatment of angina pectoris patients. It is considered to be a life-saving drug and is sold under different brand names.

An approximately 1,500-word leaflet, besides the references of 22 'scientific' books of one of the companies producing the above drug has only this to say about the side-effects of the drug :

'Side-effects other than occassional typical vascular headaches are not common in effective dose.... Histological (microscopic) examination of the tissues from animals did not reveal any evidence

of toxic injury as a result of administration of the drug'. In fact, says the leaflet, 'the increased exercise tolerance produced by the drug usually results in a gradual lowering of psychic influences, and often gives the patient a new feeling of well-being.'

The leaflet refers only to two possible side-effects, 'headache during the early phases of therapy' which 'disappear within one week of continuous, uninterrupted therapy'. Secondly, 'mild gastrointestinal disturbances might occur rarely with larger doses. These could be prevented by taking the drug with food'. Lastly, the drug 'should be given with caution to patients having glaucoma (severe eye problem).

The women packers who work on these drugs, sorting and filling the tablets into bottles, however, have a different story to tell, "See how our faces are swollen up. This line always gives up problems. Our heads ache, — throbs all day and night. We feel giddy". "We don't feel like eating at all, no appetite, nausea and constant headaches.". . . . "Our monthly period is also affected. Very heavy flow and sometimes two periods in a month."

One of the women operators told us the case of one woman, who had had two healthy children and no family history of abnormal children, had a child who was completely deformed and died a couple of days after birth. This woman had worked on the Isosorbide dinitrate line all through her pregnancy. After this incident, however, the women decided that no pregnant woman should work on the line.

The department where this drug is packed is a small 121X81 room, where 8 workers work together at sorting and filling of the bottles. The sorting woman shakes the tablets in a scoop and the powder flies into the air everytime she does it, at least about 20 times in a minute. The room is air-conditioned with no natural ventilation and with a weak air-conditioner and exhaust. The masks given to the women are very thin, white pieces of cloth and quite ineffective. The women have to stop working every few hours in order to go to the dispensary to get aspirins or simply to breathe air free of the Isosorbide powder. The women cannot explain about this too often, as the management might insist on reducing their trips to the dispensary and push them for more production. So everything remains unofficial - the doses of aspirins, the swollen faces, the fits of dizziness and nausea.

Workers have no access to correct information

The standard scientific books about drugs state the following : "Of 42 patients with agina of efforts given sorbide nitrate, two-thirds suffered from side-effects which included headaches, malaise (feeling of illness), vertigo (dizziness), dyspepsia (indigestion), nausea, epistaxis (bleeding from nose)" (Martindelle.)

"In 14 patients, sorbide nitrate when given 5 milligrams sublingually, headaches occurred in 20% of the patients (Martindelle) "Reports of ankle oedema associated with Isosorbide therapy" (Martindelle).

"In some individuals, the blood accumulates in abdomen and lower limbs, venuous return of the blood to the heart is grossly reduced and the cardiac output and blood pressure fall precipitiously. The reduced supply of blood to the brain may cause fainting preceeded by nausea, shivering, cold sweats. The most likely side-effects of Nitrite therapy are methaemoglobinaemia (which results in breathlessness after exertion), serious hypotension (low blood pressure) and headaches". (Lewiss' Pharmacology.)

"Nitrites can affect ureteral and uterine smooth muscles . . " (Goodman Gilman).

This scientific information obviously tallies more with the experience of the women workers than with the leaflet put out by the management. But the day-to-day experience of the women has had up to this day not much of an effect with the management as there is very little easily available material which the women may use to back up their own genuine problems. To begin with, there is hardly any material or research done on the actual effects of the drug on the producers themselves. The little research that we could obtain with difficulty concerned only the consumers of the drug. And even this was not easily available. The leaflet that is given with the drug is obviously misleading and far from the truth. The labour institutes, chemical directories and chemical abstracts do not list these effects at all. It was only after a great deal of scanning through medical books that the above scant information could be compiled. How are workers who work for 9 hours at the factory and the women workers who have an additional shift at home, supposed to know what it is that they are working at every day ?

There is obviously a monopoly of information and a systematic campaign of misinformation by the management. The management has its own experts, expertise and can handle knowledge and information and use it for its own purpose. If the

workers have to have some control over their own situation, they have to have their own channels of expertise, information and initiate campaigns on that basis.

The hitherto most stable organisations of the workers have been trade unions. The trade unions, however, especially in a country like India, have not been stable and confident enough to take up issues like health of workers seriously and consistently. It is a fairly new dimension and more effort needs to go into such a systematic insistence on issues like health.

On the other hand voluntary health groups are a comparatively new phenomenon in this country. *These health groups have concerned themselves mainly with the consumsers of drugs and not the producers*. This may be so because as individuals interested in health issues, their day-to-day contact is with the consumers. In fact, unless there is such a conscious perspective, health issues of producers may not be addressed at all.

When, however, it comes to the question of the health issues of women workers, there is an additional dimension to the entire perspective. A special focus on the special effects on women workers at the level of research as well as that of campaign can be effected through the insistence of women's groups at the workplace.

These three types of organisations and groups have various meeting points and can come together over very concrete demands and campaigns, which in fact have been suggested by the workers themselves.

The immediate demands in this particular case may be :

1) Immediate research into how the drug enters the system of the workers and its effects. Dissemination of this research; (2) Easy availability of the currently available research; (3) Regular monitoring of the health of the workers; (4) Well-ventilated, larger work-rooms; (5) Proper exhausts; (6) Comfortable and effective masks; (7) Gloves; (8) Rotation in work schedules and new recruitment, so that no woman receives effective, harmful doses.

Much of the work process in the packing of Isosorbide e.g the sorting and filling of the tablets is manual. While sorting the tablets and while filling them in bottles by the scoop, the tablets have to be shaken. This give rise to the powder flying in the air, which the women breath in. Alternately this process is automated, the women will have to fill the hopper which should be covered with a lid to prevent the powder from getting into the air. By automation of this process, less powder will fly and secondly less women will be required to do the work, which in turn will result in a lengthier rotation cycle. If for e.g 54 women work on the product, in rotation, each batch consists of say, six women. There are nine batches with each batch working for three days a month on Isosorbide.

If the process is automated, only three women would be required per shift to work on the product. There could then be 18 batches, working for only one-and-a-half day a month on Isosorbide. The health problems of those working would be considerably reduced as they would be working for less days as well as the atmosphere in which they work would be less contaminated. The workers would, however, have to see to it that the production norma are not increased, which is a common demand of the management in cases of automation. For these demands to be worked out, it is necessary that women workers having similar problems have an opportunity to come together to share their experiences at work and evolve a common strategy. As of today, the women workers do not have a platform through which they can begin to do this. The formation of plant level women's committees and inter-factory women's committees could act as such a platform where women workers could share experiences and take up collective campaigns on common demands.

Campaigns could be initiated to plan and attempt the implementation of alternative production processes centred around the interests of the producers and consumers. And until this alternative is implemented, the above immediate steps have to be realised so that the ill-effects of working on a life-saving drug may be minimised for those who are producing it.

This article is based on research done for the Union Research Group, Bombay, (Bulletin issue 3), and for the Society for Participatory Research in Asia, Delhi.

THE STUDY OF WOMEN, FOOD AND HEALTH IN AFRICA

meredeth turshen

A study of women's health and nutrition must be rooted in a consideration of land tenure, food production, food distribution, processing, preperation of meals, preservation, storage and consumption viewed as a system. This article, a chapter in a recently published book (see Perspective) seeks to show how economic and political decisions (in this case, in Tanzania), affect women's health status and nutrition. Some of the fundamental causes of malnutrition and disease are, it is felt, beyond the control of African women, and some causes are rooted in the structure of the global economy as it operates at the level of the village economy. The author studies the situation of women's health using theory which is interdisciplinary and historical and offers a new, more comprehensive analytical framework.

The common approach is to look at women as housewives, usually within the confines of a single discipline. Medical anthropologists, for example, typically study the rituals surrounding marriage, birth and death; they catalogue taboos that influence health, such as prohibitions of certain foods during pregnancy and prescriptions of intercourse after childbirth. We are critical of this approach because it results in a static view of society, one that lacks reference to the historical past or political present, one that isolates the local economy and stereotypes women.

In our view the problems of the health and nutrition of women and their families cannot be understood or solved if they are analyzed at the level of the household economy alone. A multidisciplinary approach is needed, which combines the interests and insights of economics, sociology and political science. Looked at through these lenses, women emerge as farmers and marketers, wives and mothers, members of cooperatives and political activists. Women's contribution to the village economy is linked to national and even international economics, in this analysis. These linkages are made necessary by the fact that some of the fundamental causes of malnutrition and disease are beyond the control of African women; some causes are rooted in the structure of the global economy.

The research methodology and analytical framework of the multidisciplinary approach are described in part one. We begin by laying out schematically the relationships between food production and nutrition, between women and health. An explanation of the theoretical underpinnings of the argument follows. In part two the approach is applied to the current situation in Tanzania, where food shortages threaten to lower the nutritional status of families.

How to Study Women's Health

The study of women's health starts with their nutrition which, together with land tenure, food production, food distribution, processing, preparation of meals, preservation, storage and consumption, must be considered as a system. (Note : The United Nations Research Institute for Social Development is carrying out a research program called "Food Systems and Society" that uses this approach). This is because, in the rural areas of Africa, agricultural productivity — in its broadest sense, from plant seeds to the meal served — determines nutritional status. Unfortunately, it is rarely the case that food production and nutrition are conceived as a system; all too often agricultural planners ignore the problems of food consumption and nutrition, especially in countries where cash crops are grown for export (World Bank, 1981).

If the relationship between food production and nutrition is a conceptual one, that between woman and food production is an observed fact in Africa. In many countries the food system centers on women who perform most of the manual labor at all stages of the production process. (Note : The argument for considering food and nutrition as a system together with women's role in agriculture is made in a report prepared for the United Nations Protein Advisory Group [Eide et al., 1977]. As long ago as 1928 Baumann observed that the field work of subsistence farming in Africa is done exclusively or predominantly by women. Yet planners continue to ignore women in their role as farmers and they treat the food women grow for domestic consumption differently from export crops. Even when the commodity is the same—for example, rice and maize are both food crops consumed domestically and cash crops raised for export—and even when women work on both garden plots and cash plantations, their contribution is disregarded. Despite much rhetoric since International Women's Year about involving women in development, male planners persist in designing improvements in cash crop production for male farmers. Barbara Rogers (1979), in her study of development planning, castigates the policy makers of

bilateral and multilateral aid agencies for their discrimination against women.

A concommitant problem with agricultural inputs is that of the very land being farmed. Patterns of communal land tenure, dating back to the pre-colonial era, have changed in this century; under systems of private property now obtaining in many countries, women lose traditional land rights. Where there is land scarcity, as in the coffee farming areas of Mt. Kilimanjaro, male competition for land suitable for cash crops pushes women off their maize shambas and vegetable plots.

The relationship between nutrition and health is one of synergy : nutrition is the basis of good-health and the determinant of the outcome of most diseases. Malnutrition both increases susceptibility to infectious disease and influences the course and outcome of illness. (Note : Resistance to infection is determined by a number of host factors, but a significant variable is the adequacy of immune response; available evidence suggests that cellular immune response and antibody synthesis are two mechanisms by which malnutrition can depress host resistance [W.H.O., 1972]). The interaction of nutrition and infection varies with the type of disease. At one end of the spectrum are diseases not dependent on nutritional status, like tetanus of the newborn, smallpox, and most of the vector-borne infections, although nutrition does affect case fatality rates. At the other end are most of the communicable diseases of childhood, diarrheal diseases, and respiratory infections—the incidence and outcome of these are very much conditioned by nutritional status. It is this latter group of diseases that is most common in Africa and claims the most infant lives. Diarrheas and respiratory infections are not preventable by medical means, however, and it is in this context that the special role of women in health arises.

Women are the providers of informal health care : as wives and mothers they are often called upon to nurse the young and the old, the sick and the disabled. Even as the network of rural health services expands in some parts of Africa, women still undertake the work of primary prevention by preparing meals, drawing water, bathing children, washing clothes, clearing the compound of refuse, and gathering fuel to light fires on cold nights in the mountainous areas of the continent.

This traditional form of informal health care was subject to contradictory pulls in the colonial period. On the one hand, the need for it grew as new types of work gave rise to new health problems and as the public and private sectors of the colonial system failed to provide adequate welfare or social services (Turshen, 1977). The need was especially great in those subsistence areas to which male migrant laborers returned when old, ill or unemployed. On the other hand, women's informal nursing skills were undermined as health care was socialized (in the sense of being performed as a service outside the home) in government and missionary clinics and as traditional medical knowledge was devalued and replaced by western medicine. Demand for home care was rising at the same time as traditional medical knowledge, especially of herbal remedies, was declining

These, then, are the relationships between women, food and health. Our next task is to make explicit the theoretical underpinnings of the analysis. To build a complex argument such as this, it is necessary to draw upon theory that facilitates the process of relating information from several separate academic disciplines—in this instance, agricultural economics, medicine, public health, and women's studies; in other words, there is a need for theory that encompasses interdisciplinary studies. A second need is for historical method, because there is no adequate explanation of the current development dilemma in Africa without reference to African history. Colonial accounts of the last century are not useful substitutes for the combination of oral history and anthropological field work that gives Africans the central role in their own stories.

Third, one needs theory to make sense of contradictions, which seem to abound in descriptions of Africa. One narrow example from African women's history will serve as an illustration. A number of authors (Boserup, 1970; Robers, 1979) have made convincing, if damning, critiques of the education given African girls by Christian missionaries. The emphasis on home economics (interpreted as cooking and sewing), not only belittled the African woman's understanding of her familial environment, but also taught her to want European manufactured goods that were often inappropriate and beyond her means. Yet if one reads the biographies of today's African women leaders, it is interesting to note how many of them are graduates of such classes, or are the daughters of women trained in this way.

Finally, one needs theory to explain the social oppression of women, their subordinate political position, and their economic expolitation. To make

sense of the realities of women's lives in a sophisticated way requires theory that differentiates the nature of constraints on a woman like Jihan Sadat from the actual existence of a poor village woman living in rural Egypt.

To sum up, the theory employed is interdisciplinary, uses historical method, relies on dialectics to analyze contradictions, and combines feminist theory of women's subordination with Marxist theory of class conflict. Hypotheses based on this body of theory are best tested in participatory research. (Note : Sources of information on participatory research methodology are the International Council for Adult Education in Toronto and the United Nations Research Institute for Social development in Geneva). In participatory research, the subjects become the research workers by defining their own problems, gathering empirical data, experimenting with solutions, and using the results to refine the analysis of their problems. This technique is particularly important for women who are too often cast as passive recipients of development programs or, at best, as respondents in surveys. Participatory research empowers women in a way that traditional methods, including participant-observation, can never do. It also has the advantage of speeding up the process of returning research results to the people most directly concerned.

With these research tools it is possible to analyze the international situation in African countries and find out how women, food and health are linked to the economic, social and political system. Internal analysis is insufficient, however, since the national system is subject to international control. One form of international control is neocolonialism, which is continuing economic domination of a former colony by the metropolitan power. Many would say that Gabon is still controlled by France in this way. A more subtle form of control is exerted by international institutions like the World Bank and the International Monetary Fund which dictate the terms on which African nations can borrow money for development projects. Marxist theories of imperialism are useful in understanding international relations, including the role of financial institutions (Brewer, 1980).

Women's Health in Tanzania

There is so little information available on women in general and women's health in particular that it is easier to begin this discussion with a description of the present economic crisis in Tanzania and deduce its impact on women. In terms of levels of analysis, we will be moving from the national up to the international economy and then turning to the village and household economy. This process may be thought of as linking macroanalysis to microanalysis.

The nature of the present economic crisis in Tanzania is described in the following news report. "Tanzania's economic problems... have forced the suspension of development projects in the 1982-83 fiscal year. President Julius Nyerere said the country's small amount of foreign exchange earnings would instead be used to pay for spare parts and other essentials. Observers said that shortages had reduced Tanzania's small manufacturing sector to 30 percent of capacity, and that there were widespread shortages of such essentials as flour, sugar and cooking oil. Inflation is running between 40 and 60 percent annually. Although Nyerere had refused IMF demands to devalue the Tanzanian shilling, the currency was in fact devalued by 10 percent in March, 1982. The IMF had sought a 50 percent devaluation" (*Africa Report*, 1982b).

Why does the IMF seek a 50 percent devaluation of the Tanzanian shilling, and why does Nyerere refuse? Tanzania is unable to balance its international income (composed of export earnings and current borrowing) with its international expenses (imports and debt servicing.) There are three ways to deal with balance of payment deficits: (1) impose import restrictions or capital controls, (2) deflate the economy by reducing economic activity, or (3) devalue the currency (Block, 1977). The IMF recommends devaluation because it leaves the market open and unimpaired, and the capitalist firms that the IMF serves want to continue selling their manufactured goods to Tanzania unimpeded by import restrictions. The firms are not affected if it costs Tanzania twice as much to buy their products.

Nyerere opposes devaluation because it raises the cost of imports and reduces real wage levels. With dwindling reserves of foreign currency and unable to negotiate a loan from the IMF (with which Tanzania has been bickering for years over terms and conditions) he is forced to cut imports. The effect of the cut is to create a shortage of spare parts, which in turn reduces manufacturing to 30 percent of capacity. With machines turned off, men and women seeking employment in Tanzania's small industrial sector must be turned away, those who hold onto their jobs receive wages worth 10 percent less. A new system of financial incentives allows industry to knock an additional 10 to 20 percent off

the pay of 'idle'—that is, less productive—workers (Dimsdale, 1982).

What will be the impact on women workers? Women are concentrated in low paying jobs, in Tanzania as elsewhere; their incomes are already inadequate (Shields, 1980) . Urban women thrown out of work will spend more time cultivating their small shambos (the kitchen gardens found near all residences) and may turn to casual prostitution to supplement their incomes, according to a survery of women workers in Dar es Salaam (Bryceson, 1980).

Meanwhile, inflation is running between 40 and 60 percent a year. In North America and Europe, inflation rates of 10 percent are a cause for alarm and government intervention; the impact of rates that average 50 percent in Third World countries less able to absorb inflation is devastating. Since it falls to women in Africa to purchase the food and clothing they and their children need — and in the cities they must also buy fuel and water — inflation will lower their standard of living, including nutritional standards.

One cannot assume, however, that all essentials are there to be purchased at any price, since the article in *Africa Report* states that there are widespread shortages of flour, sugar and cooking oil. These commodities are essential to urban women. Inevitably a black market has appeared and there are reports of hoarding and corruption. According to, *New African* magazine, "Sugar at the controlled price cost Tshs 8.50 a kilo but during a serious shortage, prices can shoot up to Tshs 30 a kilo" (*New African* 1982a).

In the countryside there is a return to the subsistence economy; surpluses are being bartered rather than sold (Dimsdale, 1982). (Note : Subsistence today should not be imagined as a return to the romantic villages described in anthroplogical accounts of the colonial era. Too much change has occurred — in land tenure and cropping patterns, for example — for that past to be recaptured, if indeed it ever existed). If this means that women are now grinding their own grain, pressing oil seeds, and processing sugar cane, then their work load is increasing. One wonders which of their many other duties will be neglected and what will be the impact of increased energy expenditures on their own health.

To secure a large loan from the IMF, Tanzania has adopted a program designed to increase the coffee crop by 5 to 6 percent a year. (Note . Tanzania was unevenly developed in the colonial period, with cash crop areas receiving most of the colony's resources. The coffee areas are on the northeastern and northwestern borders where the climate is favorable. Population density is quite high in these regions). This program will deepen the crisis for women in rural and urban areas according to our analysis. To understand why we draw this conclusion, it is necessary to read reports on increased coffee production (*African Business* 1982) together with earlier notices of expected widespread food shortages and possible famine (*Africa Report, 1982a*). In 1981 Tanzanian officials predicted that food stocks would run out within a year. In January 1982, the Minister for Agriculture announced that Tanzania would need 300,000 tons of food aid. (Three months later Western nations offered 260,000 tons of emergency food aid) (*Africa Report* 1982a).

Food aid however, is not a long-term answer. Even the official agencies now admit its failure. *New African* (1982b) reported the findings of a confidential report by the European Court of Auditors, which severely criticizes the European Economic Community's food aid to Third World countries during the last decade. A few years ago such scandals were reported, not by official agencies, but by groups like the Institute for Food and Development Policy (Lappe and Collins, 1977) and individuals like Susan George (1976). Of course the donor countries are not yet ready to abandon food aid altogether; it remains a convenient way to dispose of agricultural surpluses "while profiting from the resultant political and economic influence " (*New African* 1982b).

The connection between famine and increased acerage under cash crops turns on insufficient food production. While the IMF is pushing for more land to be given over to a non-nutritive export crop, the World Bank reports that in Sub-Saharan Africa as a whole, food production per person declined in the 1970s. "Imports of food grains (wheat, rice and maize) soared — by 9 percent since the early 1906 — reinforcing food dependency" (World Bank, 1980; 3). To realize what increased coffee production means to rural women in Bukoba or Kilimanjaro where most coffee plantations are located, we must turn to the internal analysis of women, food and health at the microlevel of the household and village economy.

Studies that describe the relationsbip between women, nutrition and food production in northeastern Tanzania were reviewed by the authors of a report prepared for the United Nations Protein

Advisory Group (Eide et al., 1977). These authors conclude that although cash crop areas like Mt. Kilimanjaro are supposedly the prosperous regions of the country, infant mortality is exceptionally high there. (Note: This finding is not reflected in official statistics for Kilimanjaro Region; the discrepancy may be accounted for by the level of aggregation of government data). Infant deaths are more numerous on the mountain than on the poor maize-growing plains to the south. The authors relate this finding to what they term 'culture-specific factors' that help to determine women's position in the family (Eide, 1977 : III. 85).

Factors such as intrafamilial food distribution appear to be crucial when economic conditions are unfavorable, as they are now (*African Business*, 1982). Coffee growers receive an average price of Tshs 15 per kilo as compared with the 1981 world market price received by the Coffee Authority of Tanzania, which was Tshs 28 per kilo, and growers may have to wait as long as six months to receive payment. As a result, an estimated 30 percent of the crop is reportedly smuggled into Kenya, where the price received is six times the Tanzanian price (Dimsdale, 1982). The loss of foreign exchange to the Coffee Authority only aggravates Tanzania's crisis. In these circumstances, the tradition of differentiating between men and women's food and the custom of serving husbands large portions of meat result in nutrition problems for less privileged family members.

Prevailing inequalities in landholdings here are accentuated by coffee production. The wives of better-off farmers with more land and cattle are under less strain than women in low income groups. Wealth allows some women to ride to distant farm plots while poorer women walk. Wealthier women can hire workers to help harvest crops and to transport them, while poorer women may spend long periods away from home walking to their fields, working in them, and carrying heavy harvest loads uphill on the return journey. A little wealth also makes it easier to keep cattle and goats since cash buys lorry loads of grass, which has to be brought up from the plain to feed animals kept in stalls or tethered because there is no grazing land available on the mountain, nor is there space to grow fodder.

Cash crops are a source of income to men and in households where income is pooled — a practice by no means to be taken for granted in Africa (Shields, 1976)— women may profit and use the money to lighten their workload. But studies show that such women are a minority. For the majority of poor women coffee crops "on nearby land will force them to walk farther to grow maize on distant fields; they will have a heavier work load as food producers, less time for household tasks and a bigger struggle to provide the family with nutritious food" (Eide et al., 1977 : 11.87).

For solutions we must turn once more to the international level, not because Tanzania bears no responsibility for its internal affairs nor because there are no further improvements to be made in domestic policy, but because the ultimate determinants of solutions are external. Few countries have tried as hard as Tanzania to improve the living standards of their masses, but government plans have often been sabotaged by unfavorable international terms of trade. Yet the IMF and the world Bank do not suggest changes at the international level; indeed the degree to which they shift responsibility for economic crises to national governments is striking. The adjustments recommended by the IMF as conditions of loans are always national policy changes, which have significant social consequences. The lending policy of the IMF encourages 'loan dependency' in the same way it fosters food dependency and leads to what Cheryl Payer (1975) has called the 'debt trap.'

The World Bank's solutions, presented in the report on 'Accelerated Development in Sub-Saharan Africa," emphasizes production of cash crops for export (World Bank, 1980). The Bank claims that there is an extra-ordinary degree of similarity throughout the region in the nature of the policy problems that have arisen and in the national responses to them. (One wonders what role the IMF has played in its imposition of uniform conditions). Among shortcomings of existing policy cited by the Bank are a bias against exports and a bias against agriculture. In reading the Bank report, one experiences the sensation of deja vu; in the nineteenth century, imperialists rationalized their colonial policy with the doctrine of natural advantage. Once again the Bank seems to be advocating that African nations specialize in producing primary commodities for the nothern industrialized nations.

The countries of the Third World oppose that rationale and have submitted a program for change called "The New International Economic Order" (United Nations, 1974). It is not possible here to describe the program in detail; it may suffice to say that implementation of the program of action on trade and development of raw mateials and primary

commodities would offer Tanzania more options than that of devaluing its currency or curtailing its development programs. The amelioration of terms of trade would offer Tanzanian coffee farmers better returns on the crop they now produce, obviating the need to expand production at rates of 5 and 6 percent per annum. Improved terms of trade would also alter the economic circumstances of women and offer the possibility of better health and nutrition for themselves and their families. The New International Economic Order holds the promise of a future for Tanzania radically different from the grim one currently predicted.

a) Awakening the Women : To understand the reality of the bhutali phenomenon in all its different dimensions. (In the minds of many woman there is a lurking doubt that the bhutali may be real. This comes to the fore especially in the minds of women affected by unfortunate events and they support their husbands in the hunt for the witch). This awakening is part of the wider struggle of the women for emancipation and equality. This awakening must also form part of the general awakening of the male population. (The men too have a tremendous fear of the witch and which is the reason for the vehemence with which they act to annhilate her). Since the bulk of the population is illiterate, the process of awakening will have to make extensive use of drama, song and discussion.

b) Improved Health is the cornerstone : Because if one goes through the earlier part of this paper one notices that the event that triggers the witch hunt, is in most cases 'unexplained' disease or death. The deterioration of the adivasi health system is a major area of concern when one looks at the bhutali problem. Any effort will have to be directed to attain three goals :

i) A re-evaluation and change of the adivasis understanding of health, disease, and health care. ii) Taking health to the grass-roots in the form of more radical health care systems and creative responses to the health problems iii) Developing a local integrated system of preventive health care.

c) The Enlightened Bhagat is the Key : As the central person in the traditional health care system of the adivasis, the bhagat plays a crucial role (whether positive or negative). Hence any action for integrated creative health care would necessarily need to include the 'enlightened bhagat' (Any attempt to substitute the present with a parallel system even if it provides a superior and more efficient system would be counter-productive). Those 'enlightened bhagats' would have to be involved in a process that is geared to : i) improving diagnostic skills. ii) identification of herbal remedies and their medicinal porperties, together with methods of cultivating and preserving various herbal plants. iii) Development of supplementary skills and medicine to complement those areas where the local systems and remedies are insufficient. iv) Development of preventive health care as a system in its own right with the bhagats.

d) Education to develop scientific attitude : A consistent programme to introduce a scientific temperament coupled with the struggle against superstition should run through the whole effort which would integrate the various parts as one integrated look at life and its different processes.

This short paper tries to put forward what we are thinking and hoping to put into effect. We need assistance and co-operation at every step. Your solidarity is as necessary as our efforts. We hope you will become part of this process of struggling for the liberation of the adivasi and the women in particular.

THE 'BHUTALI' PHENOMENON
Why Are Women Hunted Down As Witches ?

kashtakari sanghatana

The Kashtakari Sanghatna is a left democratic mass organisation of marginal farmers and agricultural workers of Thane District in Maharashtra. Even while launching numerous struggles around the problems of the adivasis, it seeks continually to build-up political consciousness in its membership.

Women have been the backbone of the organisation and have consistently remained in the forefront of the movement. However the conscious struggle for women's liberation has only recently become part of the organisation's efforts. Recently, in a women's meeting, a militant Sanghathana member, forced into the background by political repression, raised an issue of vital importance to the adivasi women. She expressed her fears of being suspected as a witch. Once a courageous fighter, now apprehensive of being hunted as a 'bhutali', (witch) her predicament threw into clear relief the contradiction of adivasi womankind - power and powerlessness - reducing them to being victims of cruel inhumanity.

Till today, various problems have forced the Sanghatna to take adhoc measures vis-a-vis the torture of women 'bhutalis'. The efforts of the activists have been reduced to a battle of wits to minimise the brutality. peoples science movement groups made efforts to expose the superstition. But the 'bhutali' remains mystified and entrenched in the adivasi mind and almost defies a rational solution.

The persecution of 'bhutali' reflects the deteriorating health status of the adivasi. The challenge to evolve a creative response to the situation confronts the organisation. This reponse while being innovative and revolutionary needs to be integral to the ethos and existence of the adivasis, their symbiotic relationship to the forest and their faltering steps into modern society. The search for the 'old yet new' is just beginning.

Every single year, with almost unfailing regularity adivasi women of Thane District, become unwilling victims of a bizarre ritual which ends, in many cases, with the whole village (men, women and children) crying in a frenzy "death to the witch". In a rapid sequence of events which allow no single member of the village community to remain unaffected or uninvolved, a group of women (or in some cases a single woman) is suspected of witchcraft and, with no warning whatsoever, forced to stand trial. Put in the dock by the village males (with the village women looking on), and sometimes even in absentia, the women are tried and summarily handed a foregone conclusion : the sentence of guilty. The guilty woman (women) is responsible for the many evils that may have befallen the village. She has to take on herself the blame for all the mishaps that may have happened. She is liable for punishment. The trial is swift and final. The accused stands in the dock, already adjudged guilty. She has neither the right of counsel (any one defending her is in turn an accomplice and immediately suspect) or defence, she is neither tried nor are her pleas recorded. She stands a mute spectator to her 'trial' and a witness to her own execution.

The whole village is prosecutor, judge and jury and finally the executioner. The guilty victim is then subjected to the brutal sentence. In most cases she (they) is stoned. Sometimes death comes as a merciful release. Every single member (for fear of being identified as an accomplice and meeting the same fate) takes part in the execution of the sentence. In most cases the event remains locked in the silence of the village. In very few cases does it reach the outer world.

What is witch-hunting ? Why and how does it occur ?

Disease and death form an integral part of the lives of the impoverished adivasis. In many instances poverty renders them helpless. Sometimes several deaths plague a single family, at other times an epidemic ravages the village. On some occasions mishaps befall a village, on other occasions disease affects livestock and cattle. The adivasi wonders at these inexplicable mysteries. He searches for the root cause of these maladies. And he finds 'a witch'. He is then impelled to rid the village of this pernicious cause and hunts down the witch with uncontrolled emotion.

Incidents of witch-hunting take place the year round. But they errupt with increased intensity during the monsoon. The reasons for this spurt in witch-hunting are not hard to find.

1) Increased Starvation, Widespread Malnutrition, Lowered Resistance : The begining of the monsoons finds many adivasi families with depleted food reserves. In many cases food stocks are the balance that remains after sowing. While food has already become scarce during the summer months, the adivasi can migrate in search of work and survival. With the onset of the monsoons, work in the brick kilns, salt pans, sand dredgers, stone quarries and earth transport, comes to a halt. The adivasis return to their villages, many of them empty handed. In the villages the availability of work is almost nil, besides many have to choose between working or cultivating their own land.

The ageold recourse of the adivasi in the face of starvation was to search for food in the jungle, wild roots, fruit, leaves and tubers. With these he was able to survive and had evolved elaborate methods of de-toxifying the poisonous roots and tubers, and make them edible. He celebrated this symbiotic reliance on the jungle with the feast of 'kohli' (eating of tender shoots from the jungle). Without eating kohli, the adivasi cannot begin transplantation, (indicative of his understanding that the bounty of the forest took priority to the fruit of his own labour). Today, rampant deforestation and extensive monoulture of commercial teak varieties has drastically reduced the availability of food from the jungle and increased starvation.

The groups most affected by the growing starvation are the older people and the children, who face increased malnutrition and lowered resistance to infection.

2) Inaccesibility of Health Care, Disrupted Communication, Shortage of Money : The rains reduce movement to a minimum. Most of the villages remain cut off. ST services are withdrawn as roads become slushy. The bullock carts, inexpensive means of transport are dismantled for the rains, cart tracks through the fields no longer exist. Taking a sick person to the hospital or PHC is possible only with makeshift stretchers. Added to this is "no money" not only to travel, but also to pay for medical services because even the PHC doctors will not treat a person, however serious, free. The lack of money becomes a compelling reason for not taking the sick person to the hospital or PHC for treatment.

3) Heavy Demands of Cultivation, Illness as Incapacitation : The adivasi methods of cultivation are backward and labour intensive. Every able bodied person is required for work. The youngest children do baby-sitting, the slightly older take care of the cattle, while the others assist in cultivation. Under such circumstances, a person is considered to be sick only when he is bed-ridden and incapacited. Till such a time (till the person falls seriously ill), everyone works and is not considered sick as long as the person can work. The breakdown of health is considered important only when it becomes an impediment to work.

Most adivasis consider going to the hospital as a last resort, when all other efforts have failed. They prefer the village bhagat because he works free, while the hospital or PHC costs money. Most patients are taken to the hospital when they are very serious. Taking a person to hospital/PHC is a disruption of the work-schedule as many are needed to take the person in a stretcher or remain in the hospital to cook for the patient. Hence the gravity of the illness is important to motivate people to take the patient to a medical facility.

4) Increased Waterborne Infection : The rains wash down the dirt from the hill slopes. Water rushes down the denuded hill sides. The thick forests and undergrowth assisted in the percolation and filtration of water. Now the streams are a muddy flow, carrying with them infection. The jungle serves as a toilet for the villagers and all of it reaches the streams. In addition, the adivasis relish the fish in the streams, which for many families is probably their major source of edible protein. The tiny fingerlings are eaten without removing the entrails. While the use of powdered tamarind leaves help to destroy any micro-organisms in the entrails, possibilities of infection still remain.

To recap, this maze of insecurity and uncertainty, the tribal places unquestioning reliance on the bhagat as his refuge, hoping through him to find a way out of a seemingly hopeless situation.

The bhagat is the tribal priest and medicine man rolled into one. He is a villager like the others, who has initiated himself into 'bhagatship'. He supports himself by his work on his lands, being a bhagat brings in no income, on the contrary it is often a drain on his own time and resources. He performs the few rituals that exist in the adivasi religion. His major function, which continues throughout the year, is as healer and medicine man.

The warli religion is based on spirit worship. Some elements of hinduism have crept in, but remain on the fringes of their worship and ritual. The koknas have absorbed much more of hindu beliefs, deities and tradition. The religion of the people centres around the appeasement of the spirits whose anger the people fear. Religion does not provide any morality or enforce an ethical code.

The adivasi medicine is from the jungle. Over years of experience, the bhagats have discovered a

variety of roots, herbs and medicinal plants that they dispense to the sick. The knowledge of these medicinal plants is handed down by word of mouth. However, once the bhagat has handed down the knowledge of the various remedies, he is supposed to stop dispensing these medicines as with the knowledge he has also handed down the power and efficacy of the medicine. The system of diagnosis centres round 'knots'. The body, according to their system, consists of different knots of muscle, nerve and blood vessel. Good health is a manifestation that equilibrium prevails, with each knot being in place and maintaining the desired tension. Illness occurs when the equilibrium is affected and the knots are either dislocated or lose their required tension. The treatment for illness is either in the form of branding or consumptiom of medicine, inhalation or even tying some herbs on the body.

The bhagat, then, is the immediate and in a sense ideal solution, for a variety of reasons : he is accessible; he is known; he is understandable; he is inexpensive; he is reliable; and, he is acceptable. Hence he forms an integral part of the adivasis healing system.

The treatment that the bhagat gives is a combination of spirit worship and offering to appease the angry spirit, and the use of herbal medicine combined at times with branding. The proportion of spirit worship and dispensing of herbal medicine varies widely with different bhagats. The efficacy of the bhagat however is progressively diminishing. The reasons for the decreases in his effectiveness are largely beyond his control.

a) Deforestation and Monoculture : Large tracts of mixed forests are being felled and replaced by monoculture of teak. A teak plantation supports no other forms of flora or fauna. With deforestation most of the traditionally used herbs are difficult to find. Many bhagats decrease the use of herbs because finding the herbs is a time consuming process. The numbers of herbal medicine-men is also on the decrease.

b) Lack on Continuity : As handing over knowledge of herbs means that the bhagat loses his power and efficacy, many bhagats die with their extensive knowledge acquired over the years. The tradition is not handed down.

c) Modern Diseases and Epidemics : with migration to the slums and shanty towns on the fringes of the cities, many adivasis return with infections which are totally new. The adivasi pharmacopia can no longer cope with the new diseases.

d) Lowered Health levels : The destruction of the forests, the elimination of mixed forests (with a variety of fruit and nut trees), the disappearance of game and the general growth of the population coupled with increased exploitation has had a severe effect on the diet of the adivasis, their intake of protein, vitamins and trace minerals resulting in a general lowering of the health of local adivasi population.

Caught in a vice of growing demands on his knowledge and powers of healing on the one hand, and a growing inability to deal with new conditions both in terms of diagnosis and therapy, a significant change is taking place in the system : a) there is a distinct shift in the bhagats modus operandi, moving more and more into spirit worship and appeasement, rather than dispensing herbal medicine. b) The tribal medical system is becoming progressively ineffective and with it grows the bhagats' failure.

To the mind, the new situation is inexplicable. They do not understand the changing circumstances that contribute to its deterioration. The bhagat cannot fail because he is in continual communication with the spirits. He can do no wrong. The blame has to be fixed elsewhere. And so, the witch becomes the cause of all the calamities and mishaps that befall a family or the village.

What are the events that culminate in this brutality?

The first event that triggers-off a witch hunt is either a prolonged illness, an inexplicable death, a series of deaths in a family, an epidemic that affects the inhabitants of a village or the livestock, widespread crop disease or failure, a number of mishaps or calamities that occur, or a combination of them.

It begins with a murmur, ('there is a witch') either emanating from the bhagat's mouth or from one of the affected individuals or groups. The murmur grows into a crescendo as the word spreads. The male members of the village start to take notice, the women of the village begin to fear.

A collection is made by the villagers to cover the costs of discovering the witch. A group of villagers is assigned the task and they go from bhagat to bhagat in search of an elusive prey.

The bhagat tries out a variety of rituals, (dann herne - read the message in grains of rice; diva herne - identify the witch in the light of a lamp), vati chalavne (using a cup which 'moves' and identifies the witch), he may conduct the sacrifice of a chicken or goat and try and read the indications spelt out in the entrails. The group of villagers may go to more than one bhagat to make certain of the identity of the witch. The bhagat who identifies the witch is not usually from the same village or locality. But through careful, intelligent questioning he is able to locate

either quarrelsome women, destitute women, women with poor family support, women who are generally socially weak, midwives and so on. The bhagat then proceeds to identify the witch and generally gives a vague description of the women on the basis of the descriptions unwittingly given by the women themselves. Once an identity is given, the group of men may go to another bhagat for a confirmation. Here too a subtle process of questions-and-answers is carried out and the identity of the witch given in similar though vague terms.

Once the process of identification is over, the next step of the village is to find the woman to fit the identity. Depending on the vagueness of the description given, the villagers (male) call for an identification parade. The parade can also consist of making all the women stand on a tava (frying pan) made red hot, on the assumption that the witches' feet will not burn. Sometimes this is by-passed and the witch is pointed out by one of the villagers and supported by the others. A third possibility is all the women who come close to the description are beaten-up till they confess to their nefarious activities and their crimes.

Once a witch or witches are identified, the whole village goes through the bizarre ritual of exorcising her of the evil spirit, or her association with the goddess Himai. Acting on the assumption that she feels no pain, the woman/women are beaten with clubs, stones or whatever else the villagers can lay their hands on. No one, whosoever they be (man, woman or child), whatsoever their relationship with the culprit be, wheresoever their sympathies may lie, whatever their beliefs may be, can abstain from this brutal activity, because an accusing finger will point in her/his direction. She/he will be accused of being accomplices of the witch.

The witch/witches are beaten till she/they fall senseless. Sometimes they survive. Survivors in most cases leave the village because the sword of an encore hangs continually on their heads. If a witch dies, she is summarily buried (not burnt) and the village maintains a stonewalled silence. If news of her death leaks out to the police, the villagers settle on who will take the onus of the 'murder' and assure him with money and legal assistance and the assurance that no one will testify against him at the trial.

After the ritualistic sacrifice is over, the catharsis complete, the village settles down with a sense of release that the cause of their anxiety has been eliminated. The women still shudder at the frightening events that has shattered their lives and a gnawing fear that they could be next in line.

What does the Bhutali phenomenon represent?

At the outset, we must make it clear that the efforts to understand the phenomenon are in no way complete and need further elaboration. We are putting down our reflections as they have occured to us, hoping to organise them further as we learn more about the living and thinking and feeling of the adivasi women and men.

a) The torture and death of the bhutali, provides a bizarre ritual which serves (provides) as catharsis | a ritualistic release of tension/aggression resentment of the tribal accumulated in his experience of the many painful events that continually plague his existence, the feelings of helplessness which accompanies his efforts to resolve them, the fears and insecurities that harass him all the while, and his forced acceptance of the unwanted unacceptable events of disease, death, mishaps and calamities. Through this catharsis, he finds release without having to confront the truth of the situation and thereby is reconciled once again to the situation.

b) The torture and death of the bhutali, thereby provides a rationalisation (explanation) of the failure of the bhagat to heal, and the relative inefficacy of the medical system. This rationalisation helps to diffuse any attempts to reassess the system of healing. The process is enhanced by the subtle shift from dispensing herbal medicine to sorcery and witchcraft that has taken place in the modus operandi of the bhagats.

c) The torture and death of the bhutali legitimises the man's innate suspicion of the 'viles-guile-deviousness' of women.

(The efforts of women to develop their own means of self-defence and countering the brute force of man have always been interpreted as scheming and guile). Hence in warli society every woman is a potential witch. No woman can ever claim to be free from this cruel possibility.

d) The torture and death of the bhutali provide a mechanism that compensates man's inability to resolve the problems of his existence (the here and now), by projecting (transferring) the root cause of all that is evil (painful) in his present outside of himself (beyond). This compensation helps him to reconcile himself to his here and now, without being forced by the nature of the events into seeking a rational explanation for them.

e) The torture and death of the bhutali serves as the 'ultimate' mechnism of control of women by men. It manifests the use of brute force (mens' forte) to crush the spirit of women and keep them in perpetual bondage. The accustion of being a bhutali is

continually resorted to by man to maintain the subjugation of women. (such references can be observed even in interactions between husband and wife). The torture and death of the bhutali which takes place in the presence of women remains a constant reminder that the duty of women is to conform and obey even when the order/command is a painful death.

f) The torture and death of Bhutali hence becomes the final (definitive) seal on the domination of women by men. The threat of the acrimonitious investigation and trial culminating in a violent brutal punishment hangs continually as a sword on the head of every woman, threatening to snap at the slightest provocation

g) The torture and death of the bhutali therefore is geared towards a conclusive suppression of any act of defiance on the part of women. The bhutali can be seen as the personification of defiance to the male order (organisation) of his world. She defies their efforts to reorganise their lives according to their plan and hence deserves the brutal treatment meted out to her.

h) The torture and death of the bhutali remains a constant warning to every woman that 'any act of insubordination to male domination will meet with a violent end'. This warning needs to be reinforced from time to time and hence periodic witch-hunting expeditions serve both a therapeutic as well as a preventive function in terms of the malaise of male-dominated society namely, the presence and thinking of women.

i) The torture and death of bhutali is related to the mystique that grows round 'blood - foetus - pregnancy' in the primitive mind. The mystique develops in the sense of awe and moves into the realm of fear. The male in his attempt to control the fear, seeks to control/crush/ suppress the root cause of the fear, the women. The domiant male also revolts against the realisation of the superior position of women which comes through their power to create and sustain life. His role in the creation of life remains minimal. His refusal to admit his subordinate place finds its expression in his act of domination.

j) The torture and death of bhutali is the logical culmination of the Pure-Impure Contradiction. This ritualistic impurity is extened into the interpretation of the female principle as dark, unruly, anarchic, devious, dangerous; while the man remains pure, rational, righteous. In the 'impurity' prejudice lie the roots of torture of womankind and their death to rid society of the 'evil principle'. The bhutali is a devotee of Himai, the goddess (the only female principle in the warli pantheon) of evil. The Principles of Good and Evil are embodied in man and woman.

k) The torture and death of the Bhutali (in many cases the suin/midwife) represents the ancient rivalry between the Bhagat and the Suin. The Midwife in her role of assisting in the birth of new life has knowledge of the mysteries of life which will always remain inaccessible to the bhagat. Her knowledge brings power and draws her inexorably into the power struggle with the Bhagat who triumphs in condemning her to death.

l) The torture and death of the bhutali is a manifestation of the Principle of Good (the Bhagat-male) finally eastablishing his supremacy in crushing the Principle of Evil (the Bhutali- woman). The bhagat as tradition goes can do no wrong nor can he harbour any evil towards anyone. All wrong and evil can be born therefore only in the womb of woman, and takes physical form in the body of a woman.

m) The torture and death of the bhutali remains a flagrant contradiction in the organisation of warli society. On the one hand the two sacraments (rites of passage/initiation) namely the zoli : (tying of the cradle) which initiates the new born child as a member of the tribe and is given a name and the lagin (marriage-the rite of initiation into the perpetuation of the tribe) by which the man and woman become adult members of the tribe are both performed by adult women. The male has no effective role to play in either of these two rites. Yet which being the High Priestess of the community, the woman must be continually kept in her rightful place. The Bhutali is the warning that the Mighty can be thrown down from their lofty thrones and made to mingle in the dust. This contradiction in warli society remains unquestioned.

n) In fact, the torture and the death of the Bhutali, as has been from time immemorial, becomes the rationalisation for the failure of man to organise his universe. The bhutali becomes the scapegoat that exonarates man of his failure in exercising his 'divinely appointed' responsibility to keep order in his world.

Where do we go from here ?

It is sometimes disconcerting to discover that the fear of the bhutali is so deeply rooted in the adivasi mind that the eradication of this horrendous annhilation of women suspected as being witches defies an easy solution. And yet there must be a way out. Our own struggle to find a way out of this malaise that strikes a death blow to the awakening of women throws up five possibilies. We share them below.

(Contd. on page 87)

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved.

Each issue of the journal will focus on one theme, but it will also carry (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

Our forthcoming issues will focus on : Work and Health, Politics of Population Control, and Health and Imperialism.

If you wish to write on any of these issues do let us know immediately. We have to work three months ahead of the date of publication which means that the issue on Women and Health is already being worked on. A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. We have retained the spellings and referencing style of reprint articles. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We would also like to receive shorter articles, commentaries, views or reports. These need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be nealty typed in double spacing, on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions **in a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced on one side of the paper.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are working on issues of interest to you.

WORKING EDITORS

Please send me Socialist Health Review for one year (four issues). I am sending Rs. _____ as subscription and/or donation by Demand Draft/Cheque. (D.D. and cheque in favour of Amar Jesani or Padma Prakash, and for cheque, add Rs 5, if outside Bombay).

Give Us an Answer !

All our life is on fire, all our prices rising,
Give us an answer, O rulers of the country !

A handful of American wheat, a kilo of milo mixed with chaff
Doesn't our country grow crops
Or do we have only mud-mixed grains ?

Give us an answer.....

We have forgotten the colour of milk
Coconuts and dried fruits have gone underground
Our children have only jaggery tea for nourishment

Sweet oil for cooking is the price of gold
Coconut oil for our hair is not to be had
Without rock oil for lamps we are familiar with darkness

We burn in the summer, we are drenched in the rains
We bear the rigor of winter without any clothes
Why don't we yet have any shelter ?

We toil night and day and sleep half-starved
While the parasites fill their bellies with butter
Why does the thief get food while the owner is cheated ?

There are pastures for the cattle of the rich
For forest development land is preserved
Why is there no land to support living people ?

Tall buildings rise before our eyes
The roads cannot contain these motorcycles and cars
On whose labor has such development been built ?

We filled the jails for independence
We hurled bombs into the cars of the white men
Did we do it to fatten the sacred cow ?

When we ask for a rise in wages, for work for the unemployed
Why are we met with jail, beatings and bullets ?

Now you have taken a new disguise
And appear in the colours of socialism
But we no longer want for today, promises of tomorrow !

Now we will stand on our own feet
We will throw caste and religious differences to the winds
We call for the sisterhood and brotherhood of all toilers !

We vow today to fight with our lives
We will bury capitalism in the grave
And sound the drums of our state !

We regret that we had to withold Ray H. Elling's article on 'Industrialization and Occupational Health in Underdeveloped Countries' due to lack of space.

The views expressed in the signed articles do not necessarily reflect the views of the editors.

ASSAULT AT THE WORKPLACE

Most kinds of work can produce stress and prove to be hazardous. In their efforts to survive and thrive, early humans had to struggle with the vagaries of nature, which, on many occasions, must have proved fatally hazardous to some of them. These hazards, however, would probably not have been perceived as 'work hazards' but as a part of living. Obviously at this stage, there was a difference between 'work' and 'life'. With technological progress, however, survival gradually became less of a constant risk, and human beings settled down to the business of production, the basic means by which they existed and propagated themselves. But the technological progress associated with production had its own built-in problems, which became more apparent after the Industrial Revolution began.

Sickness and absenteeism are two words which highlight the bourgeois perceptions of health. A worker is considered to be 'healthy' when he is 'fit enough to work' and 'sick' when he is unable to 'work'. Under capitalism, therefore, health becomes equated to the ability to produce goods, a concept which dehumanises the worker and reduces him to being just a form of energy for the production process. Contrast this perception of health to that of the World Health Organisation which defines health as a state of complete physical, mental and social well-being and not merely an absence of disease and infirmity.

Wherever a new technology has been introduced the effects of the impact of this technology on ecology and human health have been recognised only many years later. The interval between introduction of this technology and recognition of its effects has, in many cases been highly detrimental to both man and his environment. This situation is likely to continue as long as vested interests exist to promote dangerous technologies in place where general awareness about the dangers of these technologies is limited.

With the increasing complexity of industrial processes, more and more hazards have begun to be recognised. The brunt of these hazards fall primarily on the working class, the actual producers of goods. When this class is looked upon merely as a tool in the production process, it is easy to understand why neglect of safety precautions occurs, particularly in countries where surplus work-force exists. It is revealing to examine in this context, two examples of safety standards set by different countries. In the industrially advanced capitalist countries, safety standards are higher and better implemented than in the less advanced capitalist countries. However it is in the socialist countries, whether industrially advanced or otherwise, that safety standards are highest. This is presumably due to the latter's commitment to preventive health care. It must be noted that a physically safe working environment is one of several factors which contribute to achieving work-satisfaction. Other factors include a harmonious 'organisation of work', control over the production process and channels of communication for workers to express their feelings about various aspects of their lives.

Let us take a look at the economics of workplace neglect. For the industrialist, ignoring the provision of a safe working environment means less economic inputs into his industry for the same production output. This saving therefore becomes, another addition to the net profit. A similar situation holds true for environmental neglect. Good housekeeping and a clean environment means more investments something which an industrialist would rather avoid if he can get away with it.

An important issue currently being debated is the question of why two different safety standards should exist for worker and public exposure to hazardous materials. Proponents of the double standards (which exists today) have used four types of arguments as justification for the status quo. These arguments have been questioned by a group from the Center for Technology, Environment and Development at Clark University, U.S.A. *(Science Today,* April 1982). I am briefly presenting the debate as it examines a number of relevant topics in work and health.

1. Proponents of the double standard argue that workers must be involved in production even if it is hazardous because it is for the larger benefit of society. Any attempt to reduce the workers' risk will

result in higher costs for the product, reduced employment opportunities, etc. This is an argument which tries to balance the wo kers' interest against larger social interests. Opponents of this social utility theory contend that there is no social justice in this view and that the hazardous exposure is being accepted with only very limited knowledge of the short-term effect of these hazards. What will the long term effects be ? And are we justified in exposing future communities to these hazards ?

2. The next argument uses the premise that certain groups of workers are better able or more specialised to face risks that others like children, pregnant women or the elderly cannot. Though on the fact of it this argument looks plausible, the face is that distinctions in workforce are not always clear cut, particulary in developing countries which have child-labour etc.

3. Compensation has been given by employers and even eagerly demanded and accepted by workers exposed to hazardous operations. This has been in the form of higher wages for riskier jobs as well as compensation for damage to health. Very often workers do not know and are not informed that a particular job is risky. This is particularly true of the chemical and dust industries. Even if we accept the principle of compensation, the fact is that the system of compensation is highly inadequate. How many asbestos workers know that they (and their families) stand a chance of contracting cancer as a result of exposure to asbestos fibres ? The majority of accidents at work and occupational illness go unreported, so in these cases the question of compensation does not arise.

More importantly one must look at the question of compensation from the viewpoint of social justice. Can a noise-induced hearing loss really be compensated ? How does one quantify the compensation for a chemically induced cancer. The problem with this kind of compensation is that it may legitimise the risks imposed on workers. A similar type of legitimisation of protection of workers is used by employers who give the milk-and-vitamin tablets formula as a sop to workers who are exposed to toxic substances.

4. Lastly, consent by workers to accept risks at their jobs is used as a justification for the double standards of exposure for workers and public. As a corollary to this argument, it is also argued that the public is unable to give consent, therefore their exposure must be lower than that of the workers. A closer examination of this argument shows that truely informed consent cannot really be given by workers. No job-aspirant is ever given a neutral assessment of the hazards of his job by his employer. More significantly for a worker, the decision to take up a particular job is based largely on economic necessity, job security and upward mobility, etc.

The feminist movement has given us new insights into women's work both in and out of the home. For long it had not been realised that family and household work done by the women could be viewed as an essential prop for the man working outside and could therefore be quantified in economic terms. Studies are now underway in India to formulate methods of establishing money values for women's work.

Mental stress from work can be brought on by disruptive work patterns which alienate the worker from his work. Productivity deals, work automations physical discomforts and fragmentation of work, contribute to the workers lack of control over the pace of production and conditions of work and can lead to severe psycho-social problems. These problems are faced even by the socialist societies of today and must therefore be closely examined and tackled.

It is heartening to note that a number of independent left groups are actively taking up issues of health and safety at work and related problems. One must note that work of this nature cannot be done in isolation only by trade unions or scientists but must be done on an integrated basis with the working class, environmentalists, members of the lay public, occupation health experts, etc. to be really effective. At first glance, there may appear to be a contradiction between controlling environmental pollution and the interests of the workers (who stand the risk of losing their jobs if polluting industries are hut down). However, it is imperative to note that here is a common interest between environmentalists and workers who must exert a concerted effort to force industries to clean up their environments both within and without the factory. Even though India is the eighth largest industrialised nation in the world, it is regrettable that hardly any work has been done in our country on work-related problems. Studies done in the US have estimated that 5 per cent of all illnesses are related to occupation. The figure for India cannot be much less and in all probability is greater considering the co-existing problems of poverty and undernutrition, a surplus work-force and almost no provision of safety measures particularly for workers in the unorganised sector.

The world economic order has had much to do with the causation of occupational ill-health. Multinationals have relocated dangerous technologies, e.g. asbestos from their own countries to other poorer nations, particularly, where there is ignorance about these technologies and there is no significant labour movement. There is a pressing need for a global information system which informs trade unions about new data on health risks, and about various news being debated on work-related problems. Neither in the curriculum of medical colleges nor in actual medical practice is there an emphasis on the detection of occupationally caused illness. Even the ESI medical scheme which deals only with workers has not instituted any major effort in occupational health.

The author wishes to thank members of the editorial collective for their comments and suggestions in preparing the editorial perspective.

Ramana Dhara

The lack of concern among workers and their unions, until recently, regarding health and safety at the work-place, the apathy and corruption of the State apparatus. The insupportable and manipulative attitude of the capitalist and managerial class and the acquiescence of the scientific and medical intellegentsia with the ruling class forms the major focus of discussion in the present issue.

Working classes, for an intolerably long period, have now been at the recieving end of the harmful effects of industrial production. that has not only alienated them from the product of their labour but also has abused and assaulted their faculties of body and mind reducing them to objects in the process of production. Health issues related to the workplace environment do not find a priority in the agenda of workers' struggles for their humane rights as participants in the productive workforce, especially in underdeveloped capitalist countries, because their day-to-day survival is still at stake.

Anurag Mehra and Sandeep Agarwal in the *Politics of Health and Safety* discuss this unequal contract between labour and capital and show how the capitalist class has successfully established an ideological framework that individualises the problem of health and safety at the workplace, therefore preventing its graduation into a social issue that could frustrate the profit-maximisation efforts of the capitalist by the issue becoming a central focus of the workers' movement.

The reporting system for occupational diseases and accidents and relevant legislation in India has been reviewed in the article, *Illness and Accident Reporting* by Jean D'cunha, Loy Rego, Mihir Desai and Vijay Kanhere of the Health and Safety Unit " Bombay. It is pointed out that, inspite of the gross inadequacies in the reporting system, the accidents reported in India are still considerably higher than most highly industrialised countries. As for occupational diseases the reporting is so small that it is negligible, even when studies by various public institutions like ICMR and CLI clearly indicate a high prevalence of diseases like silicosis, byssinosis, pneumoconiosis and asbestosis among others. The various legislations pertaining to work and health have been examined and it is shown how these supposedly pro-worker legislations are openly flouted by the factory owners in collusion with the corrupt protectors and implemantors of the law.

It is not only in traditional and modern industry that workers are exposed to health hazards. Agricultural workers too, encountrer illness-causing health situations which are peculiar to their work. The People's Health Group, Patiala describe in this article, the various hazards of agricultural work. They point out that these hazards are not so much a consequence of the introduction of new technology, as they are of the prevalent exploitative relations of production.

A. D' Mello reviews the book which has been much quoted by many of our authors in this issue- *Death on the Job* by Daniel Bergman. Although it was published six years ago, the narrative, documentation and analyses of occupational health and safety struggles in the US about work-related health issues of relevance to the growing awareness among activists and health workers.

We introduce a new 'column' *The Printed Word* which with your help can be a regular feature. On these pages, we aim to give readers a glimpse of the health scene as reported in the press. Please help us to keep track of what the dailies (especially the regional dailies) view as news, in the world of health and medicine.

newsclippings in health and medicine, january – june 1984

The Health Status

Free Press Journal, 9 Ja : Monkey fever claims 18 lives in Malnad, Karnataka. A cure for the epidemic which has been taking a substantial toll every year since 1952 still eludes the medical profession.

Times of India, 15 January : Nearly all 93 employees of the state pencil units in Mandsur district have been found to be suffering from silicosis.

The Daily, : 87 out of 150 employees of the Golden Chemicals Ltd at Dahisar, one of the largest manufacturers of bichromates, basic chromium sulphates and chromium derivatives in Bombay, are found to have developed perforations in the nasal septum, an ailment induced by inhalation of chromium salts.

The Daily, 15 Feb. : In a span of 3 years, 16 workers of the Asbestos Packing and Manufacturing company in Bombay have lost their lives either because of asbestosis or TB, cancer, and heart ailments caused by inhalation of asbestosis dust. A recent check-up by the ESIS doctors revealed that 40 out of 240 workers suffered from asbestosis with lung function disability ranging from 10 to 75 per cent. The medical factory inspector has not taken any action in the last 20 years.

The Telegraph, 24 Feb. : Mystery disease in Arunachala Pradesh kills 20 in seven days.

The Statesman, 11 Mar. : Over 6,000 cases of malaria were recorded in1983 at one centre alone in Calcutta and the total number will not be less than 15,000.

Indian Express, 23 Mar : According to a study conducted by the National Institute of Nutrition, some 600 persons out of 2000 people of 28 villages of Prakasam, Nalgonda and Guntur district of Andhra Pradesh have been crippled for life by a disease named Genu Valgum which results in bow legs. Scientists have linked this to environmental changes following the construction of massive dam at Nagarjunasagar, which raised the subsoil water, increasing its alkalinity, leading to a concentration of trace elements like molybdenum in food grains grown in the soil. These molybdenum-rich foods displace copper in the body leading to the crippling bone diseases.

The Statesman, 2 Apr. : Dysentery toll rises to 628 in West Bengal. The number of people attacked is 12, 281, the worst affected areas being Jalpaiguri, Cooch Behar and Murshidabad.

The Statesman, 18 Apr. : According to an Oxfam study, the strange physical disorder (the Handigodu syndrome) noticed in some villages of the Shimoga district in Karnataka is traceable to the consumption of fish contaminated by residues of 'endin', a parthion chemical used in paddy fields.

Free Press Journal, 24 Apr. : The Gujarat government has decided to close down the 2000-bed civil hospital in Ahmedabad, the largest in Asia. The killer jaundice has claimed 300 lives including that of 30 doctors.

Hindustan Times, 28 Apr. : More than 5, 500 cases of malaria were reported in Delhi since January.

The Statesman, 4 May : Death toll rises to 1,244 in West Bengal. Total number of people stricken rose to 32,409.

Free Press Journal, 10 May : A recent study conducted by the Institute of Genetics and Hospital for Genetic Disease Hyderabad has found that workers in rubber, pharmaceuticals and asbestos factories reveal an increase in chromosomal aberrations like gaps and breaks and chromosomal abnormalitles due to mutagenesis caused by the pollutants.

The Statesman, 10 May : Dysentery toll in West Bengal now 1,592.

The Statesman, 19 May : Dysentery toll in West Bengal now 1,875. Total number of cases is now 61,762.

Hindu, 20 May : Gujarat hepatitis toll now 531.

Indian Express, 27 May : Dysentery which claimed 2,700 lives in West Bengal, Assam, Tripura, Orissa, Bihar, UP, Himachal Pradesh, and Rajasthan continues to spread claiming 1,987 lives in West Bengal alone.

Health Policy and the Health System

Deccan Herald, 2 Jan. : An integrated health and family

planning programme is to be launched in Kerala and Karnataka with a credit of $ 70 million from the International Development Association (IDA) the World Bank affiliates for concessionary lending. The programme which includes the setting up of PHCs with a staff each of three doctors covering a 'block' of about 80,000 to 100,000 will benefit 20 million people in Karnataka and 4 million in Kerala. The government of India and the state governments of Karnataka and Kerala will provide $ 53.8 million for the project which is to cost 123.5 million dollars.

Free Press Journal, 30 Jan. A mysterious loss of eyes from a corpse kept in the cold room and awaiting postmortem at the Irwin hospital and medical college in Jamnagar has been reported.

The Daily, 13 Jan. The Maharashtra Health minister Lalitha Rao has agreed to a proposal to set up a central maintenance department of the health service to be set up for the speedy repair of medical equipment.

Deccan Herald, 2 Feb. According to a study conducted by the Trained Nurses Association of India, in most hospitals one nurse looks after as many as 50 patients and the nurse : doctor ratio is 1:3.

Free Press Journal, 18Feb. : India, the world's 'largest home of medical manpower' has lost an investment of 144 million dollars in training 15,000 physicians at present working abroad, according to a WHO study.

The Daily, 19 Feb. : The anti-corruption bureau has registered criminal cases against seven Bombay doctors who are panel men of the ESIS, for cheating the scheme of more than Rs. 4 lakhs.

The Daily, 21 Feb. : 2,000 blood transfusion bottles costing Rs. 50,000 have vanished without a trace from the Lokmanya Tilak Municipal hospital in Bombay.

Free Press Journal, 14 Mar. : A Bill proposing the enforcement of state government control over medical centres run by various charitable trusts was introduced in the Maharashtra Legislative Assembly. It calls for the appointment of not more than three nominees on the governing bodies of the trusts for supervising the working of their medical centres.

Financial Express, 2 Apr. : (*Editorial*) The five-point strategy of the union health ministry to discourage the migration of doctors cannot be faulted. The earlier ban on medical graduates going abroad for courses already available here has helped to stem the drain. The latest proposal is to ban even the sponsorship for employment abroad of certain categories of doctors whose services are required within the country.

Hindustan Times, 25 Apr. : Soshit, a legal aid society has moved a petition in the Supreme Court asking the Delhi administration to explain why it should not be directed to take care of the large number of patients dying in the Jayaprakash Narayan hospital in Delhi while awaiting treatment. The society alleges that patients from neighbouring states are allowed to die because their bodies constitute a valuable 'commodity' for the morgue.

The Statesman : The West Bengal health department has requested the Left front to take a decision on the continuation of the Community Health Service Scheme in view of the increasing availability of doctors to serve in rural hospitals. The scheme, under which a 3-year medical training is given was introduced at centres a few years ago, when graduate doctors used to refuse rural postings.

The Hindu, 20 Mar. . The government of Tamil Nadu plans to popularise the comprehensive health check up scheme introduced in 1978. Anyone can have a comprehensive check-up in government hospitals for Rs. 10 including blood tests, urine analysis, ECG, X-rays and also tests to detect sugar, cholesterol, albumen, and diseases like VD. The results are usually available the same day and a health index card is given.

Times of India, 23 Mar. : An anaesthetist at the RCF Hospital in Bombay has been held liable for causing the death of a patient due to negligence. The jury ruled in unanimous verdict, upheld by the additional coroner that the anaesthetist had overlooked necessary precautions during the operation.

Medical technlogy and developments in medical practice

Deccan Herald, 5 Jan. : Screening units in the state hospitals in Karnataka are being phased out with a view to preventing radiation hazard to patients. They are being replaced by safer devices called the Odelca cameras, 6 of which will be imported this year. Six others have already been purchased.

Frees Press Journal, 10 Jan. : 73 machines and instruments are lying idle in different municipal

hospitals and dispensaries in Bombay according to the Municipal Commissioner D. N. Sukhtankar.

The Daily, 12 Jan. : A West German organisation has sent a Rs. 28 lakh gift package comprising X-ray machines, cardiograms, dental chairs, operation tables, opthalmic instruments, infusion sets, 51 boxes of medicines and an ambulance to be distributed among organisations rendering free medical aid to the poor. The gifts are being channelled through the Shree Gadge Maharaj Mission in Maharashtra.

Financial Express, 2 Apr. : The Chittaranjan National Cancer Research Centre has decided to purchase an electron microscope at a cost of Rs. 20.25 lakhs from Hitachi, a Japanese company. Scientists at the centre have pointed out various violatious of the norm.

Indian Express, 5 Apr. : 12 out of the 92 X ray machines in government hospitals in Maharashtra were not functioning.

Hindustan Times, 10 Apr. : According to a recent WHO report, X-rays were given routinely without medical justification. So used and misused are X-rays that they constitute a major source of exposure to man-made ionizing radiation.

Deccan Herald, 24 Apr. : India would need electronic medical equipment worth about Rs. 1,000 crores to achieve health for all by 2000 A. D. According to Dr. P. P. Gupta, the Secretary to the Department of Electronics, India had produced medical electronics equipment worth Rs. 13 crores in 1982 and was expected to reach Rs. 20 crores in '84-'85.

The Hindu, 26 Apr. : Hospitals attached to five medical colleges in Tamil Nadu are to be provided with dialysers this year, at a cost of Rs. 61 lakhs. The decision was taken in view of the spurt in toxic cases.

The Statesman, 26 May . India's first indigenous body scanner will be ready for installation in September this year at a diagnostic centre in Calcutta. A new manufacturing unit, Uniscans and Sonics will be making six CT head scanners and three CT body scanners in a year.

Hindustan Times, 28 May : A Rs. 16-crore trauma centre is being planned at the AIIMS, New Delhi. It is feared that the setting up of the centre is an excuse to relocate a doctor with the right connections who will be retiring, who has not written a single paper in the last decade and more.

Deccan Herald, 12 Jun : Open heart surgery, including coronary bypass surgery need only cost Rs. 17,000 in India according to Mr. Prathap Reddy the chairman of the Apollo Hospital Pvt. Ltd, Madras which has performed about 100 such operations in less than 100 days, saving the country nearly 12 million in foreign exchange.

Protests, Strikes and Agitations

Free Press Journal, 4 Jan. : Nearly 300 students of the Tibbia Unani Medical College have been on strike since the past one-and-a-half year demanding retrospective affiliation for the past six batches to the Bombay University. Twenty students including eight girls are on indefinite hunger strikes. The College was previously conducting a diploma course in Unani medicine and surgery. The Central Council of Indigenous Medicine directed the college in 1977 to affiliate with the Bombay University, and permitted the college to start a 6-year degree course (BUMS). The college applied for affiliation, but nothing happened.

Times of India, 21 Feb : Junior doctors went on strike at a Municipal hospital in Bombay in protest of the lack of basic facilities, vital druge and essential medical equipment (including bandages).

The Hindu, Mar. : The junior doctors of the Government college in Karnataka who were on an indefinite strike to press for improvements in emergency services, drug availability and increase in stipends and other demands have withdrawn the strike on a promise by the Minister to look into the matter.

Indian Express, 12 Mar. : The agitating students of the Unani Medical College in Bombay have finally succeeded in getting affiliated to the Bombay University.

Free Press Journal, 17 Mar. : The Gujarat chief minister Madhavsinh Solanki rejected the demands of agitating medical students and striking doctors (allopathic) for cancellation of the six-month emergency medical course for homeopathic and ayurvedic doctors.

The Telegraph, 18 Apr. : Nearly 3,000 medical students, house staff and registrars and surgeons are on strike in Orissa demanding upward revision of stipends, better equipment and life saving drugs.

The Statesman, 6 May : The 24-day strike of 3.000 medical students and junior doctors in Orissa has been called off in response to

an appeal by a State-level citizen's committe.

Hindustan Times, 18 May : The strike of junior doctors of the nine medical college hospitals in Bihar has entered the fifth day today. Doctors' demands include absorption of all 4,000 unemployed medical graduates in the state health services.

Deccan Herald, 13 June : Homeopathic students of two colleges in Bangalore have ended their fast, which had been undertaken to press their demands for the government take over of the two private colleges.

The statesman, 25 June : The The 44-day strike by junior doctors which had paralysed functioning of nine medical college hospitals in Bihar has been called off on an assurance that their main demands would be considered shortly.

The Daily, 27 June : The Maharashtra Association of Junior Doctors has called for a day's token strike today. The strike will involve 4,000 resident doctors and 500 post graduate students. They are protesting against the openings of capitation fee medical college in the state.

Professional bodies in health care

The Telegraph, 2 Apr. : Efforts are under way to get the IMA registered as a union, according to Dr. V. Parameshwara, the convener of IMA's first zonal conference held in Bangalore recently.

Business Standard, 11 January : Inaugurating the 59th All-India Medical Conference the president of the IMA, Mr. J. Mathias opposed any short term or a condensed course as demanded by the Nurses Association of Tamil Nadu who had suggested a condensed course for qualified nurses to qualify as rural medical officers. He was also opposed to the change in the medium of education in medical colleges.

Deccan Herald, 18 May : The Karnataka state branch of the Indian Medical Asssociation, IMA, has taken strong exception to the state government's decision to grant permission for starting a new medical college. The state IMA president Dr. V. S. Achar said as many as 8000 medical graduates were unemployed. The state already has 13 medical colleges. More institutions are needed to train paramedical workers, but only medical colleges make money.

Deccan Herald, 24 May : The centre may soon amend the Indian Medical Council Act to put an end to the practice of charging capitation fee by medical colleges. At present there is no provison in the Indian medical council act to take prior approval of the Union government for opening a new college.

Deccan Herald, 1 June : The Homoeopathy Teaching Council of India has demanded immediate government takeover of the two private homeopathy colleges in Bangalore.

Deccan Herald, 6 June : The Karnataka state has through an executive order stopped all admissions to aided and unaided medical colleges for '84-'85 pending the framing of necessary rules under the Karnataka Educational Institutions (Prohibition of capitation fees) Bill, 1984 which has been passed by the state legislature and is yet to get the President's assent.

Compilation : P. P.

The news items have been compiled from the documentation files of the Centre for Education and Documentation, Bombay.

'TB and Society' : MFC Annual Meet

The 1985 Annual Meet of the Medico Friend Circle will focus on 'TB and Society'. The dates of the Meet are January 27 - 29 1985 and the venue, Bangalore. For further information contact : Ravi Narayan, Convener MFC, 326, V Main, I Block, Koramangala, Bangalore 560 034.

Book News

Human Stress, Work and Job Satisfaction : A Critical Approach, Occupational Safety and Health by T.M. Fraser

Series no : 50, ILO, Geneva, 1983, 15 swiss francs.

The book discusses man as a system and a system component, the psychophysiology of human stress, the needs and satisfactions of work, the psychophysiology of work and fatigue, stress mechanisms and their manifestations in work and the interrelationship between stress and satisfaction. He ends with a series of remedial suggestions

The Black Lung Movement In The U. S.

Black Lung Associations and Brown Lung Associations were two Organisations of US Coal miners and textile workers respectively. The bulk of their membership came from disabled workers or their widows and their heroic struggles paved the way for better H & S for all.

Coal mining is a hazardous occupation and one of the earliest unionisation campaigns in the mines gathered momentum in the aftermath of a serious accident. In 1869, an accident in Avandale mine in Pennsylvania killed 179 miners due to the refusal of the mine-owners to build an escape exit. Speaking to the people gathered to mourn the dead, John Siney, President of the Working Men's Benevolent Association (forerunner of the United Mine Workers, said "Men, If you must die with your boots on, die for your families, your homes, your country, bur do not consent to die like rats in a trap for those who have no more interest in you than in the pick you dig with". Thousands of people joined the Association that day !

Despite these pledges to work for health and safety, the struggles for health and safety at work were at a low key, with the struggle of the Union for survival, expansion and improvement in terms of employment being more central. As the union grew, the union bureaucracy in UMW became more entrenched. The union had a department dealing with health and safety but this was not able and did not do much to improve working conditions.

It was only the sixties that the movement for better working conditions took off. The focus became the struggle to get pneumoconiosis- "black lung"- recognised as a compensable disease. State and federal government authorities had for decades denied that coal dust was a hazard and caused disease. In the early sixties diseased workers and some socially active doctors began to tell other workers of the dangers involved. "When we found out what was actually going on,' says Bill Worthington, a leader of the Black Lung movement, "we began to get pretty angry. Coal Companies were making millions of dollers off us, and when we got too sick to work, they said we had "miners asthma" for which there was no compensation."

In November 1978, Consolidated Coal Company, Mine No. 9 in Farmington, West Virginia, blew up killing seventy eight miners. Judith Henderson, window of miner Paul Henderson recalls, "It was cold and snowy that November 20th morning when I had turned the morning news on and heard the world that were to begin a terrible nightmare. The rumour that there had been an explosion was confined, and all but 21 on the midnight shift were trapped. This was where my husband worked and where the nightmare began. We waited, hoped, prayed that our men would be saved, but in vain. On the 10th day they announced the mines would be sealed because the Company Officials felt that no human life could live after this time."

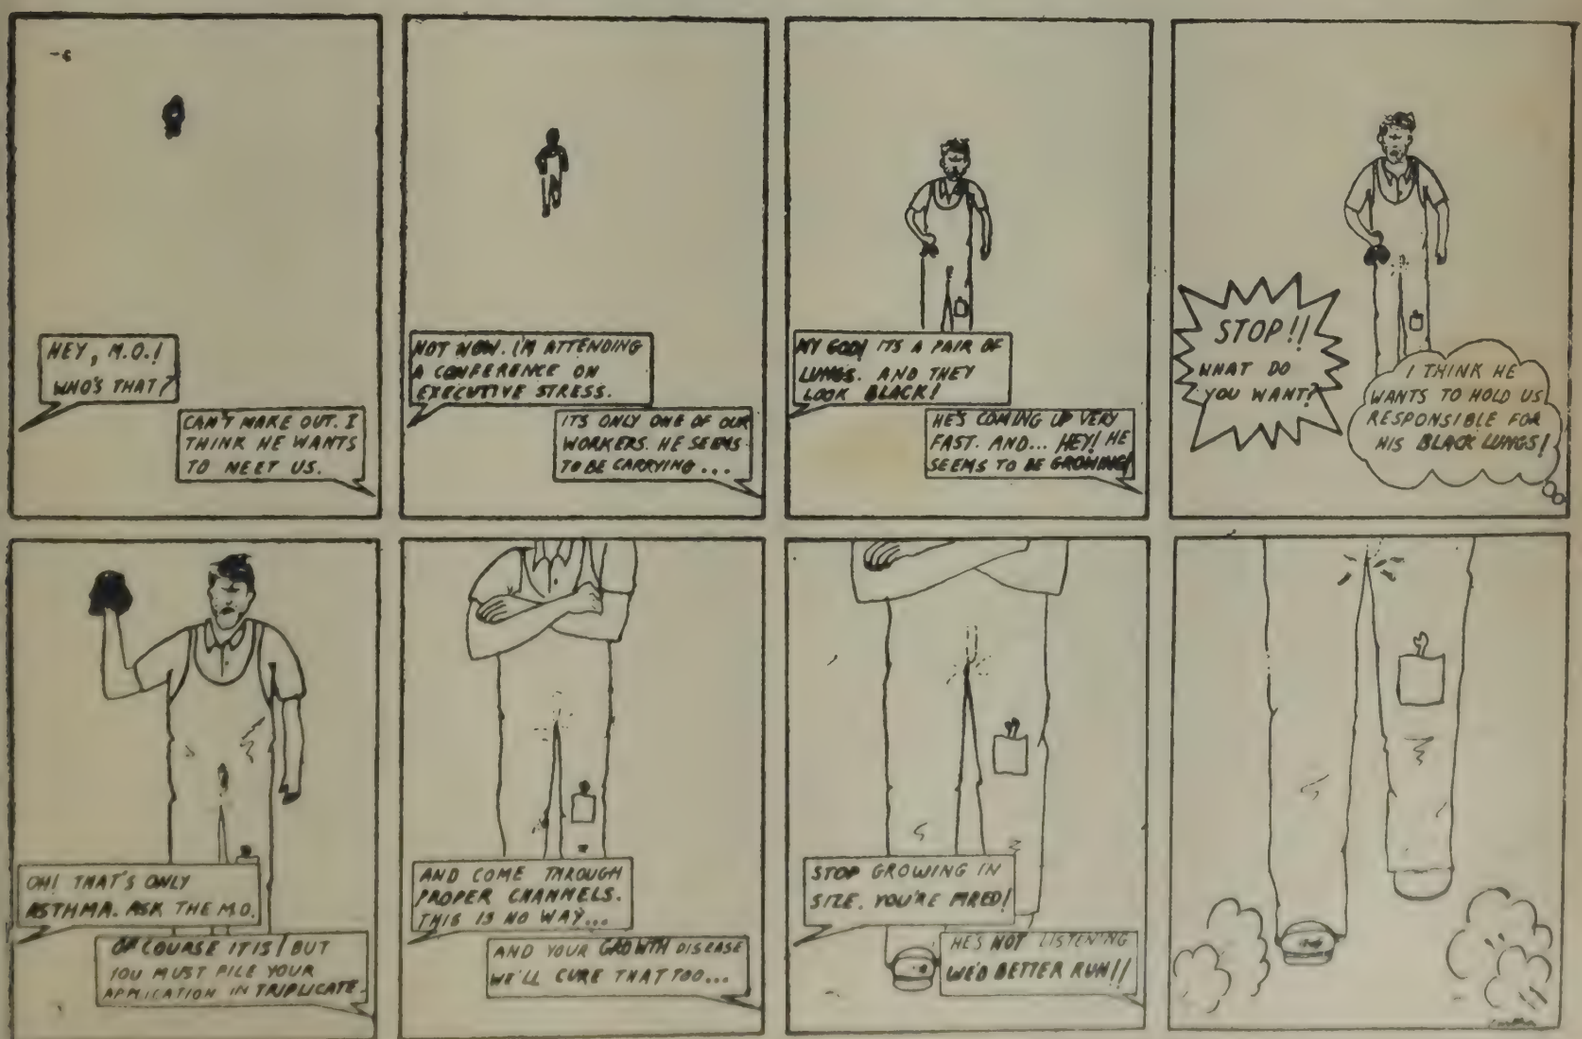
The UMW leadership took advantage of public sympathy to press for a federal mine safety law, ignoring the issue of Black Lung compensation and Occupational health - believing it would jeopordise the passage of a safety law. The Black Lung (BL) movement received a spurt in the membership and an added thrust after the Farmington disaster. The various state Black Lung Associations together with Associations of Disabled Miners and widows along with progressive physicians and lawyers pressed for BL compensation and controls on Coal dust.

In January, 1969, the Virginia (where Farmington mine is located) BL Association was formed and in February and March of that year, 42,000 of the State's 44,000 miners walked off their jobs, pressing for a new law. They marched to the State Capital and demonstrated in front of the State Legislature brandishing blackened lungs obtained from autopsies of pneumoconiosis (Black Lung) victims. The strike hailed as "the most important political strike in modern labour history" forced the first state compensetion for Black Lung in West Virginia.

In December 1969, came a new federal law, the Coal Mine Health and Safety Act of 1969, a comprehensive bill dealing with Black Lung compensation, exposure to coal dust and safety. It specified that coal miners, or their widows, could apply for permanent black lung benefits regardles of when they had quit the mines. Benefits were paid from federal tax revenues and at first 60 percent of the applicants won the benefits. The law also created a federal inspection system to enforce safety and coal dust standards.

The passage of the Act gave new stength to the BLAs. Retired miners and widows who had successfully secured benefits began to lead others through the social security maze, and consolidated themselves into effective country-level organisations. A coalition of such groups was formed for tackling specific national level political battles like the

passage of a new law, seeking to relax the medical eligibility requirements under BL benefits. The Black Lung Benefits Act was passed in 1972, under which a miner who had worked for 15 years underground was presumed to have compensable black lung, if he was totally disabled by lung disease, regardless of what X-Ray findings indicated. However, the social security administration was successful in reducing claims succes rate fram 60% to 10%.



Yet, despite limitations in the implementation of the Act, the black lung revolt has resulted in half a million families getting some financial benefit. The annual payment of a billion dollars is twenty times the total paid out for Occupational Disease for all other workers. Conditions in the mines too have improved, with annual coal mine accident deaths falling from 260 to 132 between the year 1970 to 1974.

The initiative for the BL movement was taken outside UMW, by the force of rank and file pressure. As a conscious organising strategy, partly determined by the nature of the issue, it was the old retired workers, many already ill, who were in the leadership and therefore, free from threat of company reprisals. the movement developed new strategies and a language of its own, with folk songs written about their work lines by many BL members. Two of the songs (reproduced in this issue) were written by an 83 old miner who had spent 40 years in the mines. The use of songs reflects the mass nature of the movement.

In most chemical-caused diseases, exposure is limited to a section of the work-force and very often, unless there is a vigorous educational campaign, it becomes difficult for people to recognise disease as work-related. Once the health effects of coal dust were understood, the obvious and widespread nature of the hazard was one of the reasons of the relative success of coal miners securing compensation for Black Lung. Due to the peculiar nature of the Industry, the position of the miners vis-a-vis the owners was strong. Demand for coal is high, and most coal is manufactured in mines owned by large companies with large unionised work-forces. The public too was sympathetic to the obvious hazards of the job and miners have repeatedly demonstrated their capacity to strike and shut down the mines. These factors can be identified as favouring the emergence of the Black Lung revolt.

The BL Movement changed the face of the Union movement in the mines as well as paved the way for health and safety to become an issue on the agenda of Union struggle and legislative action.

–L. R.

Politics Of Health And Safety

anurag mehra and sandeep agarwal

The unequal contract between labour and capital under the hegemony of capitalism results in the neglect of the workplace environment leading to innumerable hazards to the health of workers. The capitalist class and it's associates, like scientists, technocrats and doctors, who have monopolised the knowledge pertaining to work processes and it's consequences for the working class, have also successfully promoted a model that deals with the problem of health and safety as an individualistic and not a social phenomenon. The working class on the other hand has failed to counter this ideology, especially in backward capitalist countries, because their social and economic conditions do not permit them to go beyond their struggle for better wages.

The authors are members of the Health and Safety Group, Bombay.

Work Relations and Occupational Health

". . . labour is the workers' own life activity, the manifestation of his own life and this activity he sells to another person to secure the necessary means of subsistence. Thus his life activity is for him only a means to enable him to exist. He works in order to live. He does not even reckon labour as a part of his life, it is rather a sacrifice of his life ". . . (Marx)

The social (contract) between labour and capital grants to the owners of capital the right to maximise their profits at the cost of labour. But to the workers, it guarantees only the means to reproduce their labour power, that is, their capacity to work. The worker is thus reduced to an apppendage in the production process, yet another part of the profit making machinery that must be kept 'running' smoothly. For the worker it is not a question just of wages but of his whole experience of work which is hazardous, stressful and monotonous and leads to his physical and spiritual impoverishment. It is at this point of confrontation that labour struggles for better working conditions and organisation of work, and capital tries to minimise its cost of production by minimising its investment in health and safety and restructuring of work, thereby making it more monotonous and less skilled.

The unequal nature of this contract in favour of capital can be clearly seen from the fact that workers have little control over the conditions of work provided to them. At the point of selling their labour power workers lose a large measure of control over their health. They are ensured only wages, not the guarantee of healthy working conditions. In resisting this direct sale of health included in the sale of labour power, the working class struggles against the hegemony of capital at the workplace. Under conditions of commodification of labour power, of which health is a part, any working class demand related to occupational health is a positive assertion of its humanity.

Redefining Occupational Health

We will now examine how capital's definition of occupational health is incorporated in the outlook of bourgeois medicine itself - which lays a claim to being value free, objective and socially neutral.

But first let us look at some of the assumptions of modern medicine itself. The concept of a disease bases itself on the idea that disease is a result of biological agents and their assaults upon the body. The centre of conceptual focus is the organism. The social conditions - poverty, underdevelopment and the consequent everyday living conditions — under which diseases spread, biological pathogens grow and attack malnourished bodies are rarely the point of a doctor's attention. Likewise, this has led to the concept of technological intervention upon the body— drugs, thereby, medical aids — to destroy or cure diseases. Medicine thus believes that with more and more medical technology it can cure or control a diseased body. The social conditions themselves are not touched as the primary causatives; rather their study and elimination is not a doctor's forte.

Within this context of medical ideology then, a disease is reduced to its biological symptoms and cure is reduced to a set of technological tools. The social environment of human beings who suffer, is thought to have very little to do with disease and disability. Therefore health is seen in the individual not exhibiting any overt biological symptoms of a disease. The focus is on the individual, his body which has remained functional in doing what is expected of it, **despite** adverse conditions.

The medico-technical definition of occupational health then, would have us believe that a worker's health is merely his capability to be functional in performing his work. Indeed its origins lie directly in current medical ideology, presented above, which defines health only as an absence of disease or

disability rather than as a positive state of well being. Such an approach inevitably leads to obscuring the large range of damaging conditions to which workers are exposed but to which they have, by sheer necessity, adapted in a very perverse manner in the sense of somehow managing to live with them. But more than this a definition of occupational health of this sort serves a profoundly political purpose. It serves to absolve capital and management of their responsibility in creation of so much misery at the workplace which according to some medically 'established' notions, can be declared non-medical and hence not relating to health at all.

Our purpose here, then, is to point out that we should reject this idea of occupational health and replace it by a more comprehensive and broad notion of health which transcends the narrow idea that ill health is something that can be obviously seen and that which generally requires serious medical intervention. It is only then that long range health disorders, problems of work-derived stress and anxiety, the not so immediately apparent evey-day discomfort and alienation of the workplace, monotony and repititiveness, a lack of creative exercise and the intensity of work will become problems of occupational health. It is only this that will take occupational health beyond the realms of conventional toxicology, industrial hygiene, safety engineering and even so called industrial psychology.

All this brings us to the definitive thesis that the question of occupational health and safety is not primarily a matter of technical definitions nor is its resolution a matter of relevant control technology. It is primarily a question of the social relations of production which finally determine the social conditions of work and thus in a very direct way an outcome of the existing balance of class forces.

In essence, therefore, the question of what constitutes occupational health, its status, and recognition, primarily arise out of the process of class struggle and not out of any technical notion of health or the availability of advanced technologies. And so it follows that a resolution of this quesition is possible only through class struggle where immediate manifestations are the working class struggles for better working conditions. The struggle for better and shorter working hours and working conditions is therefore identical with the struggle for the achievement of health in relation to work.

Having thus established our conception of occupational health, we should proceed to examine some of the ways in which reality on this issue is distorted and falsified.

The Scientificity of Safety Standards

In this regard it is illuminating to examine an instance of how a dehumanised 'science' has as its content, quite explicitly, a partisan point of view in favour of 'Capital'. The 'science' under examination is industrial toxicology in general and the so called 'safety limits' for various industrial chemicals in particular. In professional terminology it is more commonly referred to as 'Threshold Limit Value' - TLV for short. Essentially it refers to that average concentration of chemical present in the environs of the worker beyond which it becomes dangerous to the worker's health — calculated by assuming a daily dosage of fixed exposure time. The dubious nature of this concept can be demonstrated at a number of levels. At the level of ideology the whole notion of such a quantifiable concept arises from a top-down approach to health, wherein the effort is to bring down the chemical concentration of exposure to acceptable limits rather than its exact reverse where the effort is to keep the level of exposure as near zero as possible. This will be clearly seen when we, later on, examine the history ot TLVs in USA.

Above and beyond this, the decision as to what constitutes a health danger in the long and short run, the method of assesment and quantification are all extremely suspect. It would perhaps be correct to state that with management-oriented professional experts the values obtained would be much higher hence more damaging to health than those obtained by a bottom upwards approach. The USSR presents a completely obverse case in this respect when compared to USA, in regard to safety limits. The attempt here is to keep concentrations as low as possible with stringent requirements on the 'Maximum Allowable Concentration' (MAC) In fact, in the USA, the lobbying that accompanies the acceptance of a legal limit, clearly brings out the political nature of the compromise the TLV represents, rather than being an objective and scientific concentration value. As an illustrative case study (quoted in Berman 1978) the history of the asbestos safety standards in USA serves to substantiate the points made above. The National Institute of Occupational Safety and Health (NIOSH) after screening through scientific data recommends a safety limit. Public hearings are then held to debate and decide upon an enforceable and permanant standard. This is the normal, time consuming and expensive procedure that is followed.

Since the 1920s the asbestos manufacturing industry has been aware of the hazards of asbestos and its connection to asbestosis and lung cancer. This however has not deterred the industry in expanding and promoting the use of asbestos even till today. The hazard is compounded by the fact that workers carry home with them asbestos dust and fibres on their clothes and person which can then affect sections of the public. The first propaganda strategy the industry adopted was to promote medical research to dispute asbestos hazards. A number of studies and data therein was suppressed and distorted till 1955 when the connection between cancer and asbestos was unequivocally established. Very promptly scientists from all of the biggest manufacturing establishments disputed this without citing any evidence to the contrary. In fact, till 1960, 63 papers on the health hazards of asbestos were published. Of these 52, which were published independently of industry, showed a positive connection between asbestos and cancer, and the rest 11 studies sponsored by industry presented opposite conclusions. The independent studies remained in scientific and technical journals, inaccessible to the public at large, and the major decisions on standards were left to the industry and a compliant government.

In 1970, with the passage of Occupational Safety and Health Act (OSHA) and the public furore created by some enlightened professionals, some scientists independent of the industry recommended a standard of 2 fibres/cm^3 of air (not larger than 5 mm in length for 8 hrs. a day). Many pressed for a total ban on the use of asbestos. In this atmostphere, since industry based denials of the hazards no longer had public credibility, the strategy was changed. The industry gradually took over financial control of most of the research relating to asbestos in a bid to monopolise all research and thereby minimise critcism of asbestos use. There was a sudden spate in publicity and the flow of funds, leaving hardly any asbestos research untouched by industry control. And even though the industry continued to flout the safety limits, even in the public eye, pressure was brought upon the government by labour to accept the standard of 2 fibres. The US government caught between the pressures of industry and pre-labour lobbies, declared 5 fibres as a temporary standard and initiated public hearings for fixing a permanent one as industry representatives at the hearings claimed that many US plants would have to be shut down if the lower standard of 2 fibres was accepted. The government hurriedly asked a private consultant to study the health effects of concentrations ranging from 2 to 30 fibres and the cost of reducing concentrations to industry. The cost of lives of the workers and the public were not considered but more than that "such economic calculations were to become a permanent part of the standards making'. The government policy was that "the cost to employer of meeting any new occupational health standards must fall within an economic range acceptable to industry". The accepted standard of 5 fibres was reduced to 2 fibres as pressure mounted but by now the NIOSH had recommended a safety limit of 0.1 fibres (1976).

Industry has reacted in many ways to these regulations. Many firms have sold over. Some others have shifted over to Mexico, Taiwan and South Korea where there are no legal limits to asbestos pollution. Many companies have paid out fabulous sums of money as compensation through lawsuits. However the president of one of the companies persisted in insisting that the problem was a technological one 'This is an industrial hygiene problem, not a problem of the public. (Berman 1978).

At the level of soundness of concept, there are numerous laws in the notion of a TLV. For instance, it does not cater to workers who may be hypersensitive to certain chemicals or who are genetically deficient in withstanding the onslaught of such workplace pollutants. The calculation assumes that the people at risk are all healthy young men, rather than women of childbearing age and elder people who have already suffered serious damage to their health. A further examination of the methods of assesment reveals even more significant facts which are, more often than not, relegated to the realm of more scientific controversy. TLVs are commonly arrived at by controlled experimentation on rats, rabbits and the like, and the consequent statistical analysis of the experimental data. These are then extended to apply to human guniea pigs - an extrapolation that has no basis whatever other than the fact that it is chosen as a basis precisely because none other exists, and one is needed to legitimise a certain level of workplace hazards if industrial production is to remain economically feasible. An illustration will make this clear. The teratogen 'thalidomide' dose required to effect a mouse is 31 mg/kg. of body weight whereas that for a human being is 0.5 - 1.0 mg/kg of body weight. If the mouse dose is extended on the body weight basis to apply to human beings, consequences can be disastrous. Still there exist a millions of chemicals for which this distinction may not be known so precisely. They must be taking their daily toll in laborateries and factories. Moreover, TLVs refer to concentrations of isolated chemicals

individually. The synergistic effects, that can result by a mixing of a number of chemicals together are not incorporated into the concept thereby making it even less representative of the hazards at the workplace.

The sanctity of science thus bestowed upon such concepts as TLVs is rather the attempt to project, as socially neutral and objective, knowledge which is overtly political.

Occupational Disease :

Yet another example of the ideological influence, in occupational health, of capital can be seen clearly when it comes to defining what constitutes an occupational disease. For a disease to qualify as being work-derived, the normal bourgeois provision in law is to prove that the disease has exclusive and unequivocal work-related origins. This indeed is a monumental task. Often it is impossible to perform since there are many diseases, not necessarily occupational, which have a lot of symptoms in common with the occupational disease. The confusion between Byssinnosis (a disease derived from inhalation of cotton dust; it affects the lungs and the respiratory system) and chronic lungs disease, is a classic example. Company doctors or management oriented safety staff have often used this confusion to mask the hazardous and disease producing effects of contaminated cotton dust. One medical inspector of factories commented, "All those with respiratory troubles in a textile mill need not necessarily be the victims of byssinnosis. Their standards of nutrition and living environment and habits may have caused the disease, which may appear like byssinnosis." (quoted in Berman, 1978). That this confusion is to some extent objective, is not derived. The above statement as a matter of facts may not be wrong in itself. The point however is that it is the starting assumption of all pre management studies.

Another ploy employed by the management is to simply give the disease a different name. In this process the blame of the disease is shifted from the condition of work to the person suffering from it. An American doctor, for instance, has this to say about byssinosis. It is best described as a 'symptom complex' rather than a disease in the usual sense. We feel that this term may be preferable, first, in order not to unduly alarm the workers as we attempt to protect their health; and secondly, to help avoid unfair designation of cotton as an unduly hazardous material for use in the textile industry, raising the fear the engineering control of it may be costly and that it may be better, therefore, to switch to some less costly material. (Quoted in Berman, 1978). The intention to protect cotton manufacturers profits at the expense of the workers' health could not be clearer. And it is also clear that the choice whether byssinosis is a disease or not, becomes a matter of political outlook, not just scientific information.

Some Aspects Of Industrial Accidents

Management theories of accident, which pose as objective sciences, are a sophisticated mixture of fact and fiction. Despite numerous variations, one theme is central to them - that workers' carelessness is mainly responsible for the majority of injuries at the workplace; that the sole capability and initiative to undertake preventive measures lies with the management. Safety, as such finds little attention in management circles. We will examine some aspects of these theories and their practical and ideological role.

The extreme form of such an outlook can be seen in the behavioural models of accident causation. The reason for accidents are thus seen in the accident-proneness of individual workers. Accident-proneness a phrase carved sometime in the early twenties, immediately became popular among industrial psychologists who claimed that workers are doomed to be tension and anxiety ridden, and therefore liable to carelessness at the workplace. Industrial psychologists, at great pains, have defined various kinds of nervous disorders existent in workers and their co-relation with actual incidence of injuries. *(Table overleaf)*

In spite of the usage of sophisticated psychological terminology, this theory very faithfully reflects the inherent attitudes of owners and managements, that workers are ignorant, careless, destructive and inferior. One does not find many overt references to such models today.

Another model pictures accidents as a culmination chain of multiple events. It is claimed that there is no single identifiable reason for accidents but a host of factors operating simultaneously. Safety films are made which depict situations that make an accident look really like an accidental occurance. A machine goes out of order. A maintainance person tests the machine, opens the guard and then leaves it running while going for a cup of tea. The cleaner passes by, accidentally dropping some piece of scrap on the gangway. An unsuspecting office clerk hurriedly crossing the gangway, steps over the scrap piece, trips and lands his hand into the unguarded running machine. Then a question is raised wisely as to who is responsible for the injury. The movie usually ends with prescriptions amounting to less carelessness and

Occupational Syndrome	Clinical or Dynamic Diagnosis Associated
Accident Syndrome	Impulsive characters anxiety reaction
Moonlighting	Compulsive personality, often with marital problems
Pulmonary insufficiency ("pneumoconiosis", "emphysema", "chronic bronchitis")	Depressive reaction, anxiety reaction, psychophysiological reaction (asthma)
Women employees	Physiological cycles
Grievance proneness	Paranoid personality, compulsive personality, depressive reaction.

Source : Powles, W. E. and W. D. Ross. "Industrial and Occupational Psychiarty" in American Handbook of Phychiatry, Basic Books, 1966

more safety consciousness on the part of workers. There are obvious ideological purposes which explanations of this kind serve. To a worker, it obscures the fact that most accidents occur because of unsafe work design, unguarded machines, faulty equipment and high work intensity. It also absolves the management of its responsibility. More than that it puts the blame on the workers, thereby preventing any protest on their part.

H. W. Heinrich, a US expert, did a massive study of 75,000 accidents and concluded that a distinction should be made between accidents and injuries. All accidents, according to him, do not lead to injuries. On the contrary they go unnoticed till a major injury is caused. He estimated that for every major injury, there are 29 minor injuries and 300 accidents without causing injuries. He, while advocating preventive measures, classified about 88 percent of the 75,000 accidents as caused primarily by "unsafe action" (unsafe action is defined as a departure from the established work procedure). The percentage thus classified can very widely depending on the investigators opinion about the extent to which physical conditions reasonably need to be modified to prevent injury. This choice is clearly political for technically, it is impossible to have a sharp dividing line. Cases which are normally identified as blatant examples of unsafe action on the part of workers can also be seen in the context of improper safety training on the one hand and increasing work intensity, monotony, fatigue, alienation on the other.

Safety engineers strongly advocate their case before the managements by professing that it is cheaper to prevent accidents in the long run. Terms like 'loss control' and 'damage control' are used to give this notion a scientific sanctity. It is maintained that accidents not only cause injuries, but also loss of property, loss of man and machine hours, stoppage of work etc.; the management therefore must invest in preventing accidents out of there own wish because they will profit by this. This is a major argument given by industries to project their self interest in taking up safety measures. Needless to say, at its very outset, their dehumanizing calculation betrays its ideological character. Cheysler Corporation of US actually did this calculation and concluded that with the costs of an accident. In a country like India, since compensation is negligible, there is no reason for companies to install safety measures, unless strong union pressures exist.

The problematic of accidents can be questioned at yet another level. Accidents are defined as notifiable only when the injured worker does not report for work within 48 hours (in India). This is in keeping with a bourgeois notion of health which believes in funcitonality, fatigue, sprains, aches, nicks, cuts, burns, minor eye injuries, loss of consciousness-all these form an important part of working life but are never included in accident figures. It is not surprising, that even by conservative estimates, if these injuries are accounted for, accident, figures will multiply at least tenfold. These aspects of quality of work are of prime concern for the workers. Cuts on hands during assembly, muscular strain and aches due to improper work-place design, specks of dust in the eye during grinding may go unnoticed by those who

don't work with machines directly. The present design of workplace is machine-centred, directed towards maximization of productivity. Even though a more safety-oriented design may not cost much the outlook sometimes of the designer and industrial engineers does not permit them to give importance to safety. Workers of course, are not granted any role in the design activity.

The present day managements try to impress upon the workers and the public at large that workplace health hazards have been reduced drastically with improved technologies and automation of production. Accident statistics are offered to confirm this. But such innocuous claims, in fact, serve a distinctive ideological function. Long range health hazards, problems of stress and monotony, the quality of working life, all are kept into the background while displaying of glittering success in accident control. By hiding long term health hazards, management attempts to lend credibility to the gradualist theory of occupational hazards, where slow technological changes are seen as determining factors in reduction of health hazards.

Management Monopolony over Information

Thus one of the ways in which Capital seeks to secure its domination over labour is by monopolising and controlling the flow of information relating to work. This is also true of information regarding health hazards and safety, especially if such knowledge can become a threat to profit.

As a case of outright concealment of true facts, the beryllium industry in the US provides a typical example. For almost twenty years industry and the Atomic Energy Commission had claimed worker exposure to berylium was harmless. Only after the death of a worker was this notion challenged. One of the pioneers of occupational medicine Dr. Alice Hamilton wrote of her findings, "With rare exceptions, industry and insurance companies withhold data on occupational disease—its character and incidence. This fact has great influence on the acquiring of knowledge of industrial illness in other as well as the beryllium-using industry in the US". The conclusions placed responsibility for beryllium poisoning with private industrialists. One of her own students wrote, "A few consultant doctors and industrial hygienists, by their publications, talks at professional societies and appearances in court, appear to have been used by some members of the beryllium industry to further what are considered legitimate economic ends." (Hardy, 1965).

We have seen in the case of asbestosis, the active dissemination of false information and aggressive promotion of research to generate this kind of information by the industry to dispute the actual hazards which were becoming known to the scientific community. In cases where adverse opinion is not strong, companies prefer to keep silent on the hazards of materials in use. For example, in two Mexican border towns employees of the US firm Amatex, engaged in the manufacture of asbestos, heard about the hazards from news accounts and not from their employer. (Castlemen and Vera, 1982). Nearer home, in Bombay, a fertiliser unit uses casual workers to perform necessary tasks in the most polluted points in the plant — where even regular workers refuse to tread. Apart from the very weak position of casual labourers, their ignorance and illiteracy helps the management in stifling whatever little resistance they may have to offer in the face of such barbaric assignments. The plants continue to pollute heavily but at the expense of a number of casual worker fatalities. Another example of the political helplessness and the exploitation of ignorance of contract workers is in the textile industry where they handle waste or clean machinery - both operations where cotton dust exposure is the highest. And according to the medical inspector of factories, 'This way quite a large group of textile workers prone to byssinosis go undetected. It is precisely ignorance of this kind, deliberately perpetrated by managements, that allows them to violate health and safety regulations blatantly.'

This practice of concealment, of cultivations of systematic disinformation, stems from a more general philosophical outlook of the management - the concept that workers have to be managed and controlled. Braverman's seminal critique of the capitalist organisation of work sums up the essence of the process, "It becomes essential for the capitalist, that control over the labour process pass from the hands of the worker into his own. This transition represents itself in history as the progressive alienation of the process of production from the worker and to the capitalist it presents itself as the problem of management" (Braverman, 1979).

The effects of 'scientific' management on the working class are manifold. Firstly the origins of work related stress lie in the deskilling of the worker, the destruction of his craft and the consequent division of labour wherein he performs monotonous, repititive operations; the seperation of execution and conception of work leads to a management monopoly over creativity. Even more

significantly it has led to the isolation of the worker behind an information barrier. His awareness and natural curiosity with regard to his work have been bullied into an indifference towards the science of his skill. Since he no longer participates in the totality of the process of production but only as a component part, he no longer feels the necessity of knowledge other than learning the most basic operations. The worker, who at one time, had his own craft journals, today needs the help of the professional to decipher the mysterious language of technology, medicine and law.

Management monopoly over knowledge is acquired at a more sophisticated level through the control over the specialities such as occupational medicine industrial hyiegene and safety engineering. One of the major political functions of such disciplines has been to mask overtly political knowledge as being socially neutral. The dominant ideology that the management inculcates within these disciplines is its own. This is made easier by the fact that most doctors are recruited to industry from private practice and start out with the anti-worker attitudes common to their class background. Furthermore by according them a low status in the management hierarchy of power, their urge for identification and conformity with management views and practice is intensified. Knowledge, thus restricted through these mechanisms in the hands of a pre-capital class becomes an instrument of power and manipulation. As one spokesman of the industry put it in relation. to workers' health : Our aim is " to keep a check of the workers' health while telling them as little as possible." (Berman, 1978)

The Ideological Function of Law

It is a common feature of bourgeois governments to enact laws which are progressive in content but which are never implemented properly. A number of reasons can account for this.

Firstly, such legislation and this is true for a number of regulations also, significantly those relating to health and safety - remains largely unimplemented because the enforcement agencies created to implement them are given very few powers. Whatever little exists as an enforcement structure is not only class based but also corrupt and bureaucratic. But that is only a part of the story. The second, and more important reason lies in the protective function of state in bringing such legislation into force. It projects the state as an authority which is above all classes and legally legitimises a certain level of anti-working class institutions and activities. It also helps to establish a certain measure of control over information and data which aids the state in regualting the issue in question in favour of capital (which it dominantly represents). To give an obvious analogy the state intervenes to 'protect' tribals with its whole machinery of police, forest officers and magistrates, from the clutches of 'extremists'. This protective function need not be carried out so forcefully and at times, offering the illusion of 'progressiveness' is enough to contain protest movements which in fact may be demanding much more.

Even though progressive legislation relating to health and safety in India or even elsewhere, represents an advantage to the working class and is often used by activists to their gain, the structure of factories inspectorate, its powers, the status of occupational health and safety legislation as well as regulations. bear out above aspects of such regulations. At the level of legislation an important point needs to be made. Such 'progressive' legislation is often flaunted in propaganda for its pro-worker content while not mentioning that pretty little is actually being done to enforce it. Minimum wages are therefore paid on paper; thousands of bonded labourers are released every year and the nation has perhaps the cleanest and safest factories in the world !

Health and Safety Policy : US vs Sweden

The most incisive demonstration that health and safety issues are political comes from a comparison of the ways in which different governments with different ideologies respond to such issues.

As Navarro rightly asserts, it is class conflict and the balance of forces berween capital and labour that dictate the policies of a nation - states, rather than any technical state of development in the knowledge of related disciplines or the attitudes of professional experts or the socalled 'national character traits'. An analytical comparison of two countries namely US and Sweden will make this clear. (Navarro, 1983)

From 1932 to 1976 the Social Democratic Party has been in power in Sweden even though in its own internal configurations there occurred changes from mild, legalistic evolution towards socialism to that of social reformism with the framework of capitalism it remained quite responsive to the pressures of the working-class and the middle, clerical and professional classes. On this situation capital has sacrificed its stinginess in short-term matters to sateguard its long-term profitability.

Consequently workers have a far greater control over their work in most respects and notably they are

adhered to. Managements tend to listen to factory inspectors and implement their suggestions for fear of closure.

In contrast, in US, almost every indictment by the factory inspector is hauled to court. The antagonism between state safety agencies and the industry is sharp and clear. And quite often owners get away with safety violations either for free or for an amount which is much less than that required for preventive measures.

These differences stem not, contary to what American Professor Kelman says, from the assertive nature of American people and their respect for individual rights, as against the much more cowed down and submissive-to-authority Swedish counterpart, but from the differences in the political outlook of the two regimes and the relative proximity to labour and capital.

There are some distinctive features in the above comparison. In Sweden the working class has acted as a coherent whole, in forcing the government to pass a large number of health legislations, and has consistently favoured the formation of laws and acts rather than indulge in private agreements with the owners at the level of the enterprise or craft. On the other hand, in the US the mode of individual agreement is prevalent which effectively neutralises the collective bargaining power of labour as a class. Even in the official setting of standards it is lobbying and bargaining that decide the level of compromise rather than a collective pressure from the working class. And to complement this on floor and plant level Swedish workers have much greater powers including the refusal to work and much greater access to the enforcement agencies than their American counterpart.

Monetary Demands and Occupational Hazards and Safety

Whenever labour demands betterment of working conditions, capital's standard response is to bargain by offering monetary benefits in exchange for that irreversible loss of health. This strategy followed by managements is straight forward since the cost of such compensatory payments is often far lower than the cost to actually improve the working conditions. For instance an extremely dirty asbestos plant in the US was fined a paltry 210 dollars for having violated the OSHA standards by a large margin ! (Berman 1978).

The relationship of monetary demands and health and safety demands becomes very complex at the level of organised struggle by the working class. To begin with, therefore, a distinction must be made between health and safety demands which talk of changing the actual working conditions and health and safety **related** demands which propose some other mode of exchange, i.e. stake a claim in the form the incentives or benefits in lieu of the occupational hazards. The myth that management perpetuates is to confuse between the two and in the ultimate analysis substitute the latter for the former. In promoting this myth capital exploits a number of other falsely held beliefs, for instance the inevitability of pollution and hazards as being inherent to **all** kinds of technology. The natural implication is that the only way in which hazards can be paid for is by monetary compensation. By making monetary benefits and allowances the exclusive point of bargaining, managements use compensation ideology firstly, to save on costs and secondly to contain more authentic and dangerous forms of working class protests. Altogether, it gives to the management a licence to pour out its hazards and effluents into the work environment. By institutionalising discontent over health and safety within the framework of its own ideology, Capital seeks to assert its ideological hegemony.

Unfortunately this ideology of compensation and insurance, which seeks to blur the distinction between when compensation should be demanded and when not, breeds quite easily in labour surplus economies of the Third World and the West. In the under-developed countries where wages are meagre, unemployment and consequent job insecurity looms large, the working class is often forced into positions of weakness. In such a milieu even the demand for minimal compensation payments can be a militant victory for workers. However, in nations like the US too unions have to fight against the fear of loss of job. But wages are not that meagre and militant union laedership, rank and file activist and the workers themselves have insisted on actual changes in working conditions. An enlightened working class has insisted on compensation as a minimal demand and a change in working conditions as an ultimate objective. This and only this will ensure that Capital cannot indulge in the unbridled purchase of health of labouring human beings.

ILLNESS AND ACCIDENT REPORTING IN INDUSTRY

A Review of Statistics and Legislation in India

jean d'cunha, loy rego, mihir desai and vijay kanhere

Abuse of workers' well-being at their workplace is a characteristic feature of industrial capitalism, especially backward capitalism, where workers' consciousness about health rights is submerged under the burden of immediate survival. The problems and manipulations associated with reporting (in fact gross under-reporting) of occupational accidents and diseases, the inert nature of laws pertaining to health and safety at the workplace, the collusion between the management protectors and enforcers of the laws and the medical profession; and the workers' and their unions' apathy towards this issue are highlighted by the authors who are members of the Health and Safety Unit, Bombay.

While the deaths in the communal riots in Bhiwandi, or the casualties in Punjab, shock the country and emphasise the horror of events, the fact that every-day, at work, many are wounded and some people die, due to industrial accidents and occupational diseases (IA and OD) produces few headlines and no danger signals. The workplace is becoming a battle-field, with casualties as severe as many a modern war; and despite this genocide of so many workers, the problem of health and safety at work is far from being a front line area of social and political concern and action in India. Exploring possibilities for action thus becomes necessary.

The first step in acting on a problem is to know about it, and understand its dynamics correctly. It is important, therefore, to know the extent of IA and OD in the country, the reasons for its occurence, and the perceptions and attitudes of the government, public bodies, industry, workers and unions to the problem.

In this article we attempt an examination of the statistics available with the government, make, an estimate of accidents and diseases actually occurring and identify and discuss the reasons for their occurence. However, in the absence of an organized health and safety movement by workers in India, the poverty of documented information on the same is inevitable. Our perceptions of the problem are thus tentative and impressionistic as they are based on a limited number of observations and interviews with workers.

Occupational Accidents and Diseases : A Statistical Profile

Every year, in India, 3-4 lakh people are injured and about 800 of them lose their lives due to industrial accidents. Table I shows these figures for 6 years. From these figures it becomes obvious that for this period, 1126 persons were injured and 3 persons lost their lives daily, due to industrial accidents. [1] In Maharashtra alone, one fatal accident occurs on the average every two days, while in Uttar Pradesh, once in three days.

Accidents cause an absence from work due to temporary disablement. For a sample year 1980, on the basis of available figures, accidents resulted in 3,322,829 (3.3 million) mandays absence from work due to disablement (ILYB 1981). Whereas 21.3 million man-days were lost due to strikes and lockouts (industrial disputes) during this period. (PBLS, 1982, 1983)

This means that there is a daily absenteeism of 11,076 workers due to industrial accidents, and on an average it takes 10 days for a person to recover from his accident. And the above figures pertain only to industrial accidents, those occuring in factories, excluding those workplaces like ports and docks, Railways and Mines. Table II shows casualties occuring to employees in Mines, Railways and Ports and Docks. Including these casualties makes the picture far more alarming raising the daily toll to almost 5 fatalities and 1228 injuries. [2]

Certain states have a larger incidence of accidents. Six states Maharashtra, West Bengal, Gujarat, Madhya Pradesh, Tamil Nadu and Uttar Pradesh, with 62.5% of total factory employment accounted for over 80% of the injuries. Rather than conclude that industries in these states are more hazardous, the statistics probably reflect a relatively better rate of reporting. But it is clear, however, that injuries themselves are on the rise. In Maharashtra, which today has the highest share of injuries, while employment rose by 40% during 1961 to 1978, injuries rose by over 100% (Nair, 1982).

Different industries have different rates of accidents, some industries being inherently more hazardous. Five industries, textiles, basic metal and metal products, machinery (manufacture), chemicals and transport equipment, with just about 60% of the total factory employment, account for over 80% of the

injuries. Textiles, the oldest industry in the country, with 24% of the total employment has the highest share (54%) of the injuries. In fact, injuries in the textile industry have increased by 626% between 1951 and 1978, while in that period, employment has grown by only 38% (Nair, 1982).

Nair's article shows that both fatal and non-fatal industrial accidents have been rising over the last 30 years. Fatal injuries rose by 225% from 248 in 1950 to 806 in 1980 and non-fatal, even more sharply by 393% from 76,000 in 1950 to more than 355,000 in 1980. He argues further that this cannot be explained as a result of industrial expansion alone, as accidents have increased relative to the rise in persons employed and increase in the number of factories. While the number of factories has increased by 388% from 32,000 in 1951 to 125,000 in 1978 average daily employment has risen by only 120% from 3000,000 in 1950 to 6500,000 in 1978 (Nair, 1982).

A comparison of rates of accidents in India and other countries is also revealing. During 1976, the number of accidents per 100 workers employed in all manufacturing industries was India (60.2) UK (34.8) and USA (24.74) (CLI)

While some statistical experts challenge the validity of the above due to different methods for reporting accidents in different countries, comparison of fatal accident rates reveals the same trend. The figures of number of fatal injuries per million man hours worked during 1979 and 1980 are (PBLS, 1982, 1983)

	1979	1980
USA	0.03	—
UK	0.03	0.03
Japan	0.02	0 01
Yugoslavia	0.07	0.08
India	0.15	0.15

Thus accident rates in India are far more than many industrialised countries.

This alarming magnitude of accidents is according to various experts, however, a gross under-estimation to say the least, in view of the numerous cases that go unreported.

Occupational Diseases :

Accidents are only one of the industrial killers. Occupational diseases are another one and compared to accidents are far more insiduous in their onset and therefore often just not perceptible. And yet, in terms of damage to health, they are as fearsome, perhaps more so.

Turning to the disease chart, Table III, shows the number of cases of occupational diseases reported all over India for the period from 1960 (last year for which statistics are available). 639 cases have been reported during these 21 years giving an average of a paltry 30 cases a year.

Table IV shows the break-up of the 98 cases of diseases reported during the period 1976 to 1980 (detailed statistics only available for this period). Out of 22 types of occupational diseases notifiable, only 11 of these have been reported during this period. Of those un-reported are such well known killers like Byssinossis, Brownlung which all textile workers are prone to, and Carbon disulphide poisoning (in rayon plants) which, as Padmanabhan's study (Padmanabham, 1983) "the Gas Chamber of the Chambal" showed, affected many workers. Noise induced hearing loss, one of the commonest and most widespread disorder has also gone unreported. And among the reported diseases only one case of asbestosis was reported in five years, when during this very period, an American asbestos company John-Mansville went bankrupt due to successful compensation suits filed against it by its workers. (Castleman and Vera, 1982).

The geographical spread of these cases indicates that out of the 22 states and Union territories, only 8 states report any cases at all. There are no cases from industrially advanced states like Tamil Nadu and Andhra or from Madhya Pradesh, Uttar Pradesh and Kerala.

Table V shows the number of cases reported under the Workman's Compensation Act 1923 for the years 1966 to 1979. A total of 1159 cases were reported during these 14 years, an average of 83 cases reported a year. For the 10 years for which break-up is available, of the 710 cases reported, 303 people died and 395 were permanantly disabled. These cases cover only five states out of the 22 states in the country, implying that no compensation for OD had been paid during this 14 year period in states like Maharashtra, West Bengal, Tamil Nadu or Uttar Pradesh. Of the 6 states from which there are reports, Kerala and Orissa report in 1 year only, Madhya Pradesh twice, Andhra Pradesh in 7 years. Karnataka is the only state reporting every year. In fact 90 percent of the OD reports are from Karnataka.

There are 22 types of diseases which are compensable under the Workman's Compensation Act 1923, for the period in question, though this has been raised to 34 since July 1984. For the years 1972 to 1980, during which period detailed statistics are

available, all 642 cases reported are that of silicosis. 638 of them are from Karnataka[3]. The other 21 diseases therefore, have never been reported or compensated.

Table VI shows the incidence of various notifiable and compensable diseases identified in the Indian environment by research studies, and indicates that 6% to 44% of workers under study are affected by various OD. To overcome the complete absence of data on national incidence of diseases an attempt is made to estimates the same from the studies done. Even conservative estimates of a few diseases from a few workplaces reveal that thousands of workers have been affected. For one disease in one industry only (silicosis in potteries) we get an estimate of 1845 cases, which is itself more than the total number of cases, reported for all diseases (1798) under both, the Factories, and Workmen's compensation acts for the relevant periods under study.

Let us consider the cases of asbestosis, lead poisoning and byssinossis - 3 dreaded and rampant diseases separately.

Asbestosis : Our estimates indicate about 1500 workers suffer from this disease nationally among those working in manufacture of asbestos cement and its products alone. Thus, workers handling finished products in other locations are also affected by disease, for which no estimate has been made yet. Only one case is reported to date under the Factories Act. In the West, because of the campaign by workers, supported by the general public, detection of asbestosis cases hase increased and working conditions have been imperoved and yet in 1978 US Health authorities estimated 5000 new cases of asbestosis due to past exposure would be detected annually till the end of this century. (Audyogjk Jeevan 5 March, 1982)

Lead Poisoning: Our estimates indicate over 500 workers to be suffering from this disease nationally in one industry alone-storage battery manufacture (Chakravarti and Dhar, 1981) Since the industry uses 40% of the total consumption of lead in India. the total figure for lead poisoning itself are likely to be much higher. Only 10 cases have been reported from Bihar, while not a single case has been reported from any of the factories or states where the study (Table VI) was carried out.

Byssinossis: Our estimates reveal that 37 thousand people are affected by this disease from cotton textile manufacture in the organised sector alone. Those working in cotton ginning, power looms and other types of textiles are excluded from this estimate. Their inclusion would raise the figure still higher and yet not a single case of byssinossis has ever been reported.

All these are but a few cases of positive 'death on the job' the proportion and intensity of which is reaching astronomical dimensions.

Why Does This Happen ?

The decapitated worker that emerges from impoverished and dehumanising work and living conditions is the legacy that industrial capitalism has handed down to us. That the wheels of such a system are propelled by profit, needs no further elaboration. In its competitive bid for survival and capital accumulation, newer production processes and products are introduced with 'cost-criteria, gaining an edge over 'health, safety and worker welfare criteria.' The increasing monetary stress, fatigue, decreased creativity, skill and control of newer work processes are evidences of the above. The numerous toxic-chemical agents, biological agents (fungi, bacteria, parasites), physical agents (noise, extreme temperatures and humidity, radiation, abnormal airpressure, weightlifting, repeated motions, shocks and vibrations) and mechanical agents, which are callously introduced at the workplace lead to further impoverishment of a worker's life. All this again is consistent with the principle of generalized commodity production, where the worker is perceived as a commodity and his capacity to labour commanding a price. Hence in a labour surplus capitalist economy, any depreciation in the health and wellbeing of a worker, arising out of his work and living conditions and leading to a drop in his efficiency and productivity at work, may be overcome by a replacement from the industrial reserve army.

Attitudes to Health and safety : The State Workers Unions and Management

It is a paradox that though the Directive Principles of State Policy guarantee the health, safety and well-being (including occupational health and safety) to every citizen, government's attitude to the problem has been callous. There is no well established Industrial Health Service Agency for occupational diseases in India. While the objectives and policy measures of government health programmes have been geared towards control and eradication of communicable diseases, curative and preventive health services in rural areas via Primary Health Centres, training for medical staff, government's

treatment of occupational Health and safety has been stepmotherly. What is also worth noting is that very little emphasis is accorded to occupational health and safety in the medical syllabus and in the training of medical personnel.

The State's piecemeal tteatment of the problem of occupational Health and Safety is further refelcted in four pieces of legislation allegedly designed to ensure the health and wellbeing of the worker.

The law regarding health and safety of workers in India, like the law in any other country must be viewed from three angles :

(a) The underlying principles behind the whole gamut of health and safety laws (In India this is achieved through the Employer's Liability Act, 1926)

(b) A set of rules defining duties meant to be imposed so as to reduce the risks i. e. the preventive angle (The Factories Act, 1948, The Mines Act etc.)

(c) The instrument to secure forms of compensation for the employee in which the rules governing liability are formulated and interpreted largely after the event, to determine the fault and then to align damages or other forms of compensation. according to the measure of the injury, i. e. the curative aspect. (This is represented by the Employer's State Insurance Act, 1958 - ESI Act and the Workmen's Compensation Act, 1923). But ultimately, law is, what law does, and hence it becomes extremely relevant to examine these laws not only with respect to their scope and formulation, but also with respect to the extent and nature of their implementation. It is also necessary to determine the governing ideology behind these laws, the extent to which they protect the worker and changes that need to be made in these laws.

The Employer's Liability Act 1926 : Prior to 1926, the governing ideology, as reflected in laws, or lack of them, was that whenever an employee, a natural autonomous individual, chooses to enter into a contract of employment with an employer - another natural autonomous individual - the employee is presumed to accept all the risks involved in the employment. The natural consequence was that an employer could not be held liable for any injury suffered by the employee even if it was due to the horrendous and thoroughly unhygenic working conditions. A further underlying principle was that in case the contract of employment imposed some liability upon the employer, he could avoid it, if the injury caused had resulted from a co-worker's or another person's negligence. This is what in legal parlance was known as the doctrine of common employment. The Employer's Liability Act abolished both these principles establishing a new and progressive principle that no employee could be presumed to have accepted any risk involved in any employment. The Act does not stop here but further prohibits any Agreement which puts even partial responsibility of an employment risk on the worker. The act also abolished the concept of common employment. The resulting consequence of this Act quite simply is that the risks involved in Employment are altogether the employer's responsibility and neither a contrary agreement with the workmen nor the negligence of a co-workman can change this position.

Though the Act as such is a radical departure from the earlier concept, it still leaves much to be desired. It is curative in nature, as it lays down the principles regarding the remedies available to the workers subsequent to the infirmity or disease but does not lay down any principle regarding the prevention of unsafe working condition. Guarantee of healthy working condition is not even laid down as a principle.

The Factories Act, 1948 : This is the only act of general applicability which is preventive in nature. It allegedly provides for positive action to be taken by the employer to ensure a safe place of work. The act however remains a paper tiger. It provides various facilities and protections to the workers at the shopfloor without affording either the woker or the Unions a right to demand the same. The workers cannot directly take a factory owner to court even if he violates all the provisions of the act. The grievances are funnelled through the Inspector of Factories. This a classic example of taking away with the left hand what is given by the right. The act and the rules which run into 300 pages or more do not contain guidelines for procedures in which grievances may be brought to the fore. There is no mention whatsoever as to how workers are supposed to demand what is due to them.

The officially recorded statistics on occupational accidents (O.A's) are based on accident reports received under the Factories Act, 1948 by the factories inspectorate, while that of occupational disease (O.D's) are based on reports received under the Workmen's Compensation Act, 1923 and the Factories Act, 1948.

The introduction to the Section on O. D. in the Labour Year Book (Compiled by the Labour Bureau,

Simla), reproduced with montonous regularity every year, notes in a tone of bureaucratic statistician's irony- "The available information regarding the incidence of O.D's is rather scanty". Horrifying though the figures for accidents are (see Tables I and II), these statistics present a picture far from the true one. The reporting of OD's has actually declined over the years while 267 cases were reported during the five year period 1960-64, only 98 cases were reported during the five year period 1976-80 (See Table III). This occurs despite the fact that the Factories Act, 1948 lists 22 O. D's which are notifiable under Section 89, making it obligatory for the factory managements to furnish information of O.D's contracted by their employees to the Chief Inspeetor of Factoris (CIF). This section of the Act also requires any medical practitioner attending on persons suffering from such cases to the CIF concerned. However, the above mentioned facts do not represent a decline in the incidence of O.D's but rather the increased inefficiency, ineffectiveness and corruption among those responsible for reporting cases and implementing the Act, right from the doctors to factory managements and Inspectors.

The character of the Factory Inspectorate and the ESIS is best exemplified by the stand taken in the case of Rajagopal, a worker from the Asbestos Company, Hindustan Ferodo, a subsidiary of the British Multinational Turner and Newall (CED, 1983). While Rajagopal was clearly found to be suffering from asbestosis by Sion Hospital, Bombay, ESI and various private practitioners found him to be suffering from Asthma while the verdict of the Medical Inspector of Factories (MIF) Maharashtra was that he was suffering from " acute bronchitis " (Behara, 1983). When a writ petition was filed in the Bombay Highcourt, he only obtained the additional relief of a freshly formed ESI Medical Board, not even composed of specialists in OD's, which gave a verdict of 'Chronic Bronchitis' (CED, 1983), and this during a period when a research study of CLI (See Table VI) showed a 36.5% Percent incidence of asbestosis.

The Directorate General of Factory Advisory Services (DGFAS) says "Many of the Factory Inspectorates are not in a position to effectively discharge their functions". This contention bears truth.

The Medical Inspector of Factories (MIF) and Certifying Surgoen (CS) are two authorities under the Factories Act charged with the responsibility of monitoring occupational health, among other functions. In particular they are responsible for medically examining workers, working in 20 scheduled hazardous operations - approximately corresponding to work places where workers may contact the notifiable diseases.

Of the 26 States and Union Territories for which statistic (1980-81) are available, 10 have no MIF at all while the remaining 16 have only 29 MIF'S totally. (Industrial Safety Chronicle, 1934). Of the 21 States and Union Territories for which figures (1980 81) are available, 12 have no CS's at all, while the remaining 9 have 15 CS's. (ILYB, 1982) While understaffing clearly indicates government's apathy, considering the technical incompetence and inefficiency of these authorities, one is uncertain about what purposes the mere appointment of additional inspectors will serve. Furthermore, the meagre remuneration too inhtbits the incentive to honest work.

It is no wonder then that in 1979 out of 1,22,931 registered factories 79,258, i.e. 64.47 percent were inspected. (ILYB, 1982)

Again the channels for the Factory Inspector to come to know of infringements like underreporting are non-existent since workers or unions do not have any statutory right or responsibility to report accidents. Where the Factory/Medical Inspector come to know of such cases informally, there are more lucrative methods of tackling the situation. This is evidenced by the fact that only a fraction of the anyway very few prosecutions are about under-reporting of CD and OA (See Table VII).

There are those factories too who submit no annual returns at all (about 35% according to one estimate) and therefore do not report OA's or OD's. (ILYB, 1982) Here too prosecutions are unheard of. Apart from this, the penalties provided for erring employers are so meagre, that even the employers who are brought to book continue to blatantly flout the law. Not only does the implementation of the Factories Act leave much to be desired, its scope and farmulation too is ridden with infirmities.

A factory as defined under the Act includes those places employing 10 or more workers and having a manufacturing process with the use of power, or places employing 20 or more workers without power. Thus with the large extent of sub-contracting in India, there are an increasing number af small scale industries which do not fall within the perview of the Act. They are not statutorily bound to comply with the act and therefore do not report OAs or ODs. The construction and Transport Industries too do not report OAs under the Act, though they are

the most hazardous and accident prone. The definition of a "factory" thus excludes a major portion of the working class in India from the scope of the Act.

The act extensively deals with cleanliness, lighting, protection from dust, fumes etc. But in most of these categories the reasonably practical measures to be taken are left to the management's discretion. This extends even to the fencing of machinery, where inspite of numerous detailed provisions being laid down it is the management that ultimately decides what is practicable and reasonably safe.

The Act also lists 22 diseases, now raised to 34 since July 1984, as notifiable diseases. The diagnosis of a notifiable disease has to be reported to the concerned authority who must ideally act immediately. However, the act provides only for curative measures. The worker has to wait till he actually and indisputably contracts a disease, which at times may even be fatal. Nothing can be done if merely symptoms of the disease, howsoever strong, are observed. Again numerous diseases, like skin diseases are excluded from the schedule of notifiable diseases. Problems like strain, backache and the like are not taken into account as they are not considered to be serious occupational hazards.

Furthermore, the State Governments are invested under Section 90 of the Factories Act, with wide powers to direct an enquiry into any case where a notificable disease has been or is suspected to have been contracted in a factory and "may, if it thinks fit, publish, this report or extracts from it." These powers have rarely been exercised and when they have, the Government taking advantage of the 'may' in the provision, has "thought it fit" to let such reports gather dust on shelves.

Thus due to the way the law is structured and the ineffective structure existing for its implementation, it remains a toothless monster, guaranteeing little or no protection to a worker's health and safety.

The Workman's Compensation Act. 1923: This Act is designed to provide compensation for OA's and OD'S.

That labour power in a capitalist society is a commodity is most sharply evident in the Workmen's Compensation Act. A table in the act stipulates a measured sum of money to be paid for various injuries. The human body is clinically divided into various organs and sections of organs and predetermined amount is provided as compensation for the loss of each section (See. Table VIII).

This may appear to be a detailed and minute synthetic analysis of the loss of earning capacity of a workman But this analysis indicates a totally dehumanising and utilitarian approch towards the workman. Each small tip and portion of his body is valued purely in monetary terms. Each part of his body contributes a stipulated amount to his earning which was to be equally compensated if he loses that part. The worker is thus viewed not as a human being but as a factor of production. In the event of an accident, which ideally should never occur, the employer must be compelled to provide alternate employment to the worker in additon to monetary compensation. Further the employer must be made penally liable for every accident that occurs. But above all there must be a stringent enforcement of safety norms. These suggestions arise from the content and manner in which the Workman's Compensation Act is implemented, because, under the present framework, the labour power of a worker is considered only as his means to economic survival and not as a life activity which distinguishes a human being from other living beings. Even with respect to the monetary aspect, all workers are considered together regardless of the peculiar life situation of individual workers. Monetary compensation is paid irrespective of their family needs, nature of job, promotional prospects etc.

Again a workman is entitled to compensation only if he is bedridden for a minimum of three days leaving numerous other injuries which affect the worker during the course of employment beyond the pale of this Act. The thinking behind this provision appears to suggest that a workman is injured only if he is unable to produce commodities, on the other hand, if the injury does not hamper the production of commodities, it is no injury.

Under this Act an employer is not held responsible or liable if a worker wilfully removes his personal protective equipment or any other safety mechanism provided. This is of special importance in Indian Factories, where in a few factories that provide safety equipment the equipment is often of a sub standard quality or unfit for use. It is often even found to cause further occupational hazards-for instance masks provided are often times so clumsily and badly designed that within no time of wearing them, the worker begins feeling uncomfortable or breathless.

Again the reportings of OAs and ODs for compensation under this Act is grossly short of actual occurences. In 1979, 91 cases of OD's were

reported under this Act. They were all silicosis, cases from Karnataka. Two of the 91 workers who died as a result were compensated with Rs. 8000 each, while the other 89 workers who were permanently disabled were paid Rs. 1890 each. (ILYB, 1982)

This serious under-reporting is once more indicative of the lethargy, incompetence, and inadequacy of the enforcement agency, the corrupt collusion between factory managements and the lacunae in channels for collection and compilation of data and the definition of injury in the Act.

The Employees State Insurance Act : The Act provides an employee with sickness, maternity, disability, benefits and the like. It applies to factories using power and employing 20 or more workers. Even in these factories, it covers only those employees earning less than Rs. 1000/- per month. The Act does not apply to seasonal factories and of the factories that remain, the Government is vested with the power to grant exemptions. Thus like the Factories Act, it excludes a large section of the workforce from its purview.

An Employee State Insurance Board, acting like 'the big brother', is formed under the Act. A Standing Committee and other local boards are further constituted under this. The Board consists of 40 members five of which are surprisingly worker representatives. This is comprehensible in view of the fact that they are not elected even by a farcial contest, but nominated by the Central Government. The 40 members include two medical persons as well, nominated by the Central Government; so much for an act that deals purely with medical aspects.

The Act provides for a joint contribution by the employee to be paid into a common fund. All employees governed by the ESI act must be compulsorily insured. Four types of benefits are available to them viz (1) maternity benefit, (2) disablement benefit (injury or disease in the course of employment), (3) dependants benefit (in case of death of an employee due to injury in the course of employment), and (4) medical and funeral benefit. The funeral benefit of course cannot exceed Rs. 100/-.

These benefits however cannot be availed of unless an employee has contributed for atleast 13 months to the common fund. In the event of an injury in the course of employment, occurring within 13 months, for instance, of his employment, he is not entitled to any benefits under the Act.

The Corporation is empowered to demand more money from an employer if it believes that an unhygienic factory environment or violation of health regulations is raising the incidence of ill-health to a proportion higher than what it should be. It, ofcourse, has no right to enforce the stipulated health and safety norms. Again medical benefits which are paid in cash require indisputable proof of illness. Evidence beyond a doctor's certificate is needed to establish that a worker was ill.

Also benefits under different heads cannot be claimed simultaneously. What this implies is that if a woman on maternity leave falls ill, she has to choose between the maternity benefit or the sickness benefit. She cannot encash both. Further, a worker entitled to benefits under this Act, cannot claim them under any other Act, including the Workmen's Compensation Act. Besides, prolonged illness of a worker may result in his employer dispensing with him lock, stock and barrel.

In the case of a dispute, various courts have been constituted under this Act. Red tape, nepotism and bureaucratic delays are all that the functioning of these courts offer to employees.

Finally the ESI Scheme functions with little or no infrastructure to provide even basic medical treatment. Most workers thus regard it as good for obtaining a bogus medical certificate but useless to cure any illness, let alone occupational disease. A perusal of these acts reveals that they do not even perform the role of paper tigers A bare reading of them suffices to indicate (a) that they exclude a major portion or segment of the workforce from their scope (b) Workmen are not granted sufficient rights to enforce the privileges occurring to them, (c) the privileges themselves are few and far between (d) the personnel in the enforcment department are not socially committed, nor are they technically equipped or numerically adequate to grapple with problems.

Furthermore, corruption and a management-oriented ideology that permeates the enforcement agency, prevents the rights and privileges of the workers from becoming a reality. Within the management frame of thought, a worker is perceived as a machine who must keep on functioning. In a country like India where the supply of such a 'machine' outstrips demand, the enforcement agency does not care a straw to ensure the functioning of 'the Machine' nor does it care for its breakdown.

To conclude one may assert that though the laws are far from adequate, there are certain rights and

privileges granted to a workman, which if enforced can help ameliorate their situation. The irresistable conclusion is that in a country like India the struggle for enforcement of these rights is as important as the struggle for better laws.

Let us now turn our attention to workers and management who are directly concerned with the problems of occupational health and safety.

Workers

Workers' perceptions and responses to the problem of occupational health and safety is noteworthy. Consistent with the notion that opressed groups adopt the ideological formats and practices of the oppressor, workers and unions too, have internalised Management concepts and values concerning health and safety. Health is viewed by them as the absence of disease rather than general physical fitness and well-being. It is perceived as a private issue dependent on each individual being's physiological and psychological makeup and the unique ways in which they respond to disease-causing agents like germs and microbes. The vehement emphasis by management on a worker's unsafe action as the primary cause for workplace accidents also individualises the issue of safety. Cure, within this framwork, for the injury or the malfunctioning organism is supposed to restore health. This too becomes privatised. Again health and health services are not recognized as rights but commodities whose availability depends on the individual's purchasing power. All this only serves to mask the social and political roots of health, shifting the onus of health and safety to the individual worker. Collective struggle by workers for better health and safety conditions, facilitating greater worker control over the work process and thus upsetting the balance of power between labour and capital within the overall political struggle is thus curbed.

Worker's internalisation of such a perspective cannot be merely attributed to a management conspiracy. It serves to also create for workers possibilities and guidelines for human action giving rise either to an attitude of peace and acceptance or to struggle against existing health and safety conditions. Workers response to occupational health and safety thus covers a wide spectrum ranging from stark ignorance to powerlessness, apathy, individualism and consumerism rising consciousness and a desire to struggle.

In a third world country like India, the combined effect of a dust-infested work environment together with poverty, malnutrition, insanitary living conditions, environmental pollution, alcoholism, smoking and drug-intake, brings about a synergistic effect, causing so called classical occupational disease like pneumoconiosis in coal miners and asbestos workers, byssinnosis in cotton textile workers and bagassiosis in sugar-cane crushers. A worker thus often finds it difficult to discern between ill-health caused due to poor living conditions and his occupational environment. For example, at a recent workshop on occupational health in Bombay, the comment of a socially conscious trade union activist working in a Kanpur textile mill is telling "We definitely feel uncomfortable working amidst cotton fibre and high relative humidity. Many of us have T.B., which we always assumed was due to our living in slums and poor living standards. But only after this doctor here told us of byssinossis do we know that it is the cotton fibre which is disabling us".

Again certain occupational diseases like cancer are slow and insiduous in their onset, and manifest themselves after a long time, often towards the end of the worker's career span or after he retires. He thus remains unaware of the damage done to him in the course of his work, eliminating all possibilities of struggle.

The worker is often ill-informed or ignorant of the products and materials he handles and hence unaware of the impact it is likely to have on his health. Even if he is mildly conscious that his work environment is responsible for the deterioration of his health, he lacks precise knowledge regarding the specific nature and extent of damage to his health or the medical remedies he can resort to. He thus, for instance, succumbs to milk or polyvitamin prescriptions by managements as a panacea for respiratory problems caused by inhalation of zinc fumes and dust. Due to his own backwardness or his preemption from technical and engineering know-how regarding industrial health and safety, he is not only unaware of the precise health and safety, status of his work place but also the available pollution control measures, possible safety mechanisms and safer substitute materials that management can very well introduce. He thus swallows the management bait, particularly that advocated by the chemical industry management that work hazards and pollution is inevitable and bearing with one's lot is the only alternative.

Again in the wake of unemployment and tight economic constraints, acquiring and maintaining a job is of foremost importance to a worker, regardless of health hazards at work, even if he is aware of them.

In the much exploited unorganised sector, the demand for unionisation and higher wages assumes precedence over health and safety. The fear of termination of services in the event of being declared medically unfit by the medical inspector of factories often inhibits workers from demanding medical examinations or raising health demands.

The organised and better paid workers though in a more objective position to take up health and safety issue, have by and large failed to do so. If an incentive scheme (productivity linked wage or piece rate) is under operation the workers may themselves not report minor injuries and just continue working, sometimes even without first-aid. If there are group incentives for production or even safety (award for million man-hours worked without an accident), group anxiety to acquire the bonus may pressurise the injured worker not to report the accident but to resume work as soon as possible after first-aid. Health and safety is thus preempted from being taken up as an issue.

Workers also fear plant shut-downs to rectify hazardous conditions in the work environment. This inevitably implies a loss of wages and a cut in overtime payment if any. They thus refrain from raising health and safety demands.

Finally, it is only when facilities consequent on an accident (i. e. paid special leave and compensation for disablement) are significant financially that workers make a particular effort to atleast report accidents, however small. In most companies, however, accident prevention facilities are not particularly good.

For the above reasons a number of health hazards never enter the official records of even the factory, in the first place, let alone being raised as an issue by workers.

Health and safety action has however been observed in certain dust prone chemical and engineering industries because of the high and severe incidence of diseases like asbestosis, silicosis and lead-poisoning or serious injuries and deaths resulting from work place accidents. These occurrences have shaken workers into realising the gravity of the situation and the danger to their health and lives.

The workers have resorted to an aggressive propaganda on a specific incident and the hazardous work environment through posters, pamphlets, news-items, gate-meeting and personal talks with other workers. The Unions have raised demands for medical examination of all workers, inspection and assessment of work environment and the right to obtain medical and factory assessment reports. Pressure has also been put on the management to control pollution and provide workers with personal protective epuipment like respirators, masks, goggles, gloves, overalls and safety boots. Safety guards and fencing for machines have also been demanded. Workers have also pressurised the management to set up a Safety division and safety committees within the factory. Even in these industries where health and safety has been taken up as a struggle issue, it has often been translated into a monetary demand in the form of compensation or a hazard allowance. It is interesting to observe that workers in an engineering industry did not use the gloves and protective equipment provided. They sold good quality protective footwear or wore it out of the work environment. Safety guards were removed from machines to complete production quotas in shorter periods and escape from work place. This is symptomatic of the discomfort caused by protective equipment through the long hours of work, lack of adequate awareness regarding safety, habituation to sparse clothing and working in slippers, the prestige and status of using shoes out of work, and an alienation, monotomy and boredom which preempts getting away from work as soon as possible even at the risk of one's safety.

Workers and their unions are thus permeated by the corporate culture. They are steeped in individualism, economism, consumerism and bureaucracy. Workers and their unions perceive man as an 'economic man' rather than envisaging the total intellectual, emotional, political and socio-cultural development of the human being. They have also internalised management attitudes and values to health and safety. This coupled with the deteriorating economic situation has prompted unions into preoccupation with day to day problems of workers like wages, leave, reinstatement and the like. Traditional unions have failed to take stock of technological and work process changes that bring in their train new problems and open up new areas of demands. Even if unions are aware of this, a leap from economic demands to health and safety issues would involve demands like change in plant outlay, use of substitute products, installation of safety devices and pollution control equipment. This would mean a greater control over the labour process, essentially a political demand which managements would fight tooth and nail, against

unions who would refrain from stamping too hard on management's toes. Defeat on such demands or neglect of every day problems of workers who have not yet perceived health and safety as an issue could mean loss of workers support or loosing out to a rival union Unions would refrain from this risk.

Health and safety action therefore wherever initiated has been sporadic and timely, coinciding with the occurrence of the catastrophe and petering out with the meeting of demands. It has not yet become a consistent and cohesive class-based movemement.

Management

Management's response to the problem of occupational health and safety is broadly governed by cost considerations and the strength of the union. Action has spanned from flagrant abuse of health and safety stipulations of the Factories Act, collusion with officials to punitive measures against workers, to sophisticated ideological and institutional co-optation, to progressive measures which work in the interests of management and appease workers.

Non-registration of factories, failure to submit returns and records to the factory inspectorate, flouting of TLV limits for dust, toxic chemicals, and physical agents, absence of appropriate pollution control measures, use of hazardous materials and obsolete machines, non-provision or provision of substandard personal protective equipment, absence of safety guards and fencing for machines, lack of proper canteen, sanitation and clean drinking water facilities, poor plant layout and bad housekeeping, absence of periodical medical check-ups for workers or regular inspection of factories are but a few open transgressions of the law. This is indeed effected with the active connivance of the factory inspectorate officials through personal and political favours and backdoor cash receipts.

Furthermore, management withholds from workers information regarding the process of production, materials used in production and their effects on health, number of accidents, hazardous locations, pollution control records, toxicity levels, investigative reports of accidents, factory assessment and medical reports and recommendations for improvements made by the factory inspectorate and government agencies.

Health and safety demands are often mht with management's emphasis on the inevitability of works hazards. collusion with medical personnel to give inaccurare medical reports or refrain from attributing a worker's ill health to his occupational environment is yet one more method of containing the workers. placating ignorant workers with medicaments and beverages, or monetizing the demand with a paltry compensation or hazard allowance and cash incentives for accident-free records are often resorted to by managements. Transfers, plant shutdowns, or retrenchment of workers on medical grounds after a medical examination is an oft used preventive measure. Isolationist tactics like transfer of workers, keeping worker off from the plant premises by sponsoring them for out of plant training courses in health and safety, preventing workers from entering other plants during rest intervals or lunch breaks to discuss problems on health and safety is another means employed to thwart worker initiative.

A 1976 ammedment to the Factories Act 1948, provides for the appointment of a safety officer in factories employing 1000 workers or more. In Maharashtra, out of 224 undertakings required to appoint safety officers, only 97 officers have been appointed to date. This ammendment has brought about a shift in management perspective by incorporating safety in to the structure of the Corporation, thus avoiding too much interaction with outside authorities.

The safety departments which by and large consist of safety officers, assistant safety officers, assistant safety engineers, and other safety assistants are empowered to receive accident reports, investigate causes for accidents and prescribe corrective action. Often these departments lack sufficient and competent personnel. Although the inspection rounds and the issuing out of safety equipment are by and large the only occassions for contact with the workers, safety officers are often prevented from going to the shop floor and communicating with workers. They rarely record workers' complaints during their infrequent rounds. Nor do they investigate specific complaints of workers and unions.

Reporting of accidents occurs in two phases. The first is from the worker and his supervisor to the management. The second is the reporting of the accident by the factory to the FI and the ESIS. Suppression of reports takes place at both levels as we shall see.

When a worker is injured within the factory, he gets first aid from the dispensary or the first aid centre on the premises. A written report of the

accident is sent to the authority in the factory assigned the task of collecting reports i.e. fire office, personnel or Safety department where it exists.

Certain non-external injuries like back-aches or sprains may not even be complained of by the worker, and even when he obtains first-aid and fills up a report, this may not be accepted, the authorities questioning the existence of the injury as well as whether it happened at work. Where the injury is minor supervisors may not allow the workers to leave the shop. The supervisor may even refrain from reporting an accident if he is likely to be hauled up. Often first-aid may be provided in the shop and the worker asked to continue his work. In all such cases accidents are not even reported and hence not recorded. Incentive schemes, group incentives for production and safety may often prevent a worker from reporting injuries. Though in most companies accident benefits are rare, the existence of these may prompt reporting. A number of work place accidents, therefore, never enter official factory records.

On the next stage too, i. e. reporting of accidents to the Factory Inspector and ESI, there is suppression of reports, both by just not reporting certain cases, as well as by toning down the seriousness of the injury or the event, thus falsifying the report. This happens because managements are keen not to have absenteeism, to avoid payment for compensation as well as avoid prosecutions for negligence under various acts; or for even more prosaic reasons like keeping down accident rates to win national or international awards for safety performance. In the absence of statutory rights of workers to report accidents, as well as the non-submission of annual returns by managements, reportage of accidents and hence prosecutions on the same are unheard of. If the Factory Inspector is aware of the occurence of accidents more aften than not he is silenced with bribes of various kinds.

Then at the time of compilation of the OA statistics, only 'reportable' accidents (these resulting in more than 2 days disablement) are included and according to figures for one engineering company, only about 1 accident in 10 is "reportable". Thus millions of minor nicks and cuts, burns, foreign particles in eye, lumps and sprains, with less than 2 days disablement, though reported in the factory go unrecorded in the official statistics.

There is an an even more severe under-reporting of diseases as compared to accidents, the causes lying both in the detection and diagnosis of causes. Accident injuries are directly perceptible and their existence cannot be denied. Secondly, their instantaneous occurrence clearly ascertains the cause and effect relationship between accident injuries and work. On the other hand, diseases are usually systematic malfunctioning, detection of which is time-consuming, the existence of which can be doubted. Since they are slow acting, the occupational origin of a disease, or when this is accepted, its link with a particular work place can easily be denied. Government authorities point out lack of expertise as a cause. This again has its origin in the lack of emphasis on study of diagnosis and treatment of OD in medical education, and in that most doctors, in any case, lack clinical experience of detection of such cases.

As regards reporting of cases to the FI, the responsibility lies with the factory managements and doctors. Factory managements have no interest in detecting OD's and would be keen that such information does not reach the FI or their workers. Medical practitioners are statutorily required to report cases of occupational diseases they detect. The paltry penalty for non-compliance extending to a maximum of Rs 50/- proves no dis-incentive to any doctor, though needless to say no such penalty has ever been awarded. With those being the agencies statutorily responsible for reporting, it is no suprise that so few cases are reported.

With certain categories of medical practitioners other considerations operate. Doctors employed by factory management function in the interst of managements, and even if cases are detected these are only disclosed in confidential memo to top managements. In such case, particularly in larger companies, hazardous operations may be transferred out to the small scale sector. Other Industrial health or medical consultants are reluctant to certify any illness as occupational diseases, since this may antagonise the company involved and result in his removal from the companies approved panel of doctors and consequent loss of business.

The example of Rashtriya Chemical Fertilizers (RCF) a Public Sector Chemical concern, for instance, raises questions on 'management-medical collusion'. A medical exmination in 1983, of 113 of workers of the nitric Acid plant by Dr. S R, Kamat, chest disease expert of KEM Hospital, revealed that 51% of these workers had severe basal scars on their lungs. Dr. Kamat attributed this probably to the occupational environment. A subsequent examin-

nation of more than 600 workers from different plants in the RCF by Dr. Kothari of Bombay Hospital (Rao and Kothari) 1984 showed that only 10 workers had damaged lungs. There was no trace of carboxyhaemoglobin and methaemoglobin in the blood samples and strangely the damage to the 10 workers was attributed due to smoking. This is in glaring contradiction to the previous report. Further Dr. Kothari was a person of management's choice, the latter having succeeded in circumventing the union's demand of a medical panel chosen by both workers and management.

Safety Programmes of the Safety Department

The safety programmes initiated by the Safety Department stress on unsafe worker action as the cause of accidents. Worker carelessness, lack of precaution, and dare-devil tactics attributed do workers are said to be the root to accident causation. In view of raising safety consciousness, safety schemes for workers are actively advocated, thus absolving industry of blame and responsibility and averting demands for workers control over the work process.

While normal medium sized managements resort to minium compliance with the law, if they cannot bribe the factory inspector, the larger more progressive management, particularly in chemical, petro chemical and engineering industries, are more sensitive to health and safety issues as precautionary measures. The primary focus is on the safety of equipment in order to avoid losses that can accrue from accidents. Expert personnel and agencies may even be invited by management to undertake research studies on the health and safety conditions in the plant and make suggestions for improvement. The reports however remain the management's private property. Competing trends in industry to have accident free records and thus merit national safety council awards are another motivation to improve health and safety conditions.

It must however be noted, that though technical solutions like fencing of machinery and fitting of guards is resorted to with swiftness, basic restructuring of the work environment and work processes is rarely done from the safety point of view. In the final analysis health and safety action by Maganement is undertaken at management's pace, under management initiative and control, with professional management appointed presonnel on the job thus smothering worker initiative at every stage.

Thus tens of thousands of workers are injured in work place accidents. Several more suffer from occupational diseases and keep dying, while no one bothers to notice.

Conclusion

It is thus necessary for unions to begin questioning their management-oriented conceptions of occupational health and safety and begin to clearly locate the roots of occupational diseases and accidents, link with pro-worker specialists and institutions/centres on health and safety in India and abroad as well as workers in other industries in India or abroad must be created. This will help the acquisition of information with respect to one's own industry as well as other industries. It also helps build support structures and co-ordination between workers of various industries prior to and during a struggle. Furthermore, a struggle for stringent implementation of the laws needs to be made. The demand for a comprehensive law speciffically relating to health and safety may also be raised. The law must be changed to involve workers and their unions in the process of detection and reporting and providing direct access from them to the factory inspectorate and other public agencies and institutions concerned with occupational health and safety. It is necessary for workers to demand formally created channels in their unions to monitor accidents and ill health at work and demands for personal protective equipment, safety mechanisms or even basic restructuring of the work process may be raised (whenever and wherever possible).

Finally, it must be stated that a meaningful change can only come about through a revoluionary transformation of the capitalist social order and the constitution of a 'genuine workers' "State" that will ensure safe working conditions and a disease-free work environment. the formation of such a state is however a long term goal, the movement towards which can in part be initiated by certain concrete short term actions on health and safety here and now. This can become the the springboard for a consistent and consistent and consolidated health and safety movement in India within the framework of a generalised revolutionary struggle for health and safety.

Notes

1. It is assumed that there are 300 working days to the year. For this period on an average 8 persons died every 3 days. The number of deaths in Maharashtra and Uttar Pradesh respectively over these 6 years is 866 and 639.
2. For all fatalities i.e. 1405 per year, works out to average of 14 deaths every 3 days.
3. The large number of cases in Karnataka are those of silicosis from the gold mines at Kolar gold fields, where studies as early as 1947 showed a high incidence (44%) of workers affected by silicosis. The fact that a large number of cases are reported and compensated shows how widespread the disease is, as well as indicates an active workers' organisation and a functioning occupational health faculty. Further investigation is called for.
4. Estimate of this for this industry nationally = Workers employed in this industry x 0.5 x % of workers affected in sample study ÷ 100.

HAZARDS OF AGRICULTURAL WORK

A Case Study from Punjab

peoples health group

Hazards of agricultural work are not only a consequence of the intervention of modern technology, such as machinery and chemicals. More importantly, they may be traced to the prevalent exploitative mode of production and class relations. Agricultural workers encounter a wide range of health hazards — injuries due to farm machinery, fertiliser and pesticide poisoning, animal bites, electric shocks and others. This is a report of an analysis of thresher accidents recorded in one hospital in Punjab. Overwork, defective machinery, drug addiction and other such factors are also considered.

From time immemorial the issue of health and disease has been vitally linked with the total human environment (physical, biological and socio-political). This link is as important today, as it ever was. Shortcomings in the different aspects of environment give rise to specific disease patterns.

In a country like ours, most of the diseases are the result of the interaction of poor quality of nutrition, clothing, housing, water-supply, excreta disposal, working conditions, transport facilities, environment and socio-psychological interactions.

In all these aspects of life, which are vital for the health of the people, the issue of class is almost always involved directly or indirectly. The most exploited and poor classes in a stratified society like ours, are the worst victims of the various aspects of pathogenic environment. The diseases produced by various aspects of the disease-producing environment are further interlinked with each other. The diseases created by one aspect of the environment influence and are influenced by the diseases produced by other aspects of the environment. The ones placed lowest in the class hierarchy are the worst victims of this vicious cycle. The issue of class is again central in the prevention and treatment of diseases in a stratified society. The facilites for prevention and treatment are available according to the position in the hierarchy of classes.

Environment of the work place has always played an important role in the pathogeneses of disease. Over a period of time this influence of working conditions on the issue of health and disease has enormously increased because of introduction of various advanced techniques in different fields of life including agriculture. The introduction of mechanisation, high yielding varieties of seeds and the associated use of pesticides and fertilisers has increased productivity enormously. But in the present set of socio-economic conditions, which are based on callous profit earning, these techniques have brought in new health hazards also. The benefits of these techniques being used for the so-called 'green revolution' have reached the people in direct proportion to their assets. The dispossessed i.e. the agricultural workers are least benefitted. However, they have received a maximum share of the ill effects of these developments. It must be emphasised that health hazards to which the agricultural workers are exposed are not qualitatively different from those of poor and middle peasants. The reason is very obvious. These health hazards baing connected with agricultural work affect whosoever is physically involved in the work. However given the class nature of our rural society, more the hazardous work, more the likelihood of it being done by the lowest placed classes. It must be added further that in most parts of our country agricultural workers are synonomous with harijans. Thus in the hierarchy of class and caste in our rural areas the agricultural workers/harijans are much more likely to be the victims of health hazards in agricultural work than the other relatively privileged classes/castes. Ignorance and illiteracy of the downtrodden further viciates the problem.

The various health hazards connected with agricultural work are enumerated below :

(a) Injuries connected with agricultural work particularly those caused by farm machinery.

(b) Poisoning with pesticides.

(c) Skin disorders due to the use of chemical fertilisers.

(d) Health hazards of overwork, particular postures and *drug addictions*.

(e) Bites by various poisonous animals.

(f) Electric shocks.

(g) Miscellaneous, including sun stroke, heat stroke, allergies and hook worm etc.

People involved in agricultural work are highly prone to various injuries. The cause of injury ranges from compulsion to work barefoot to the use of fast moving farm machinery. Amongst the machines which are likely to cause injury to the user the wheat thresher occupies the top position. Due to this the injuries caused by the thresher machine have been discussed in a bit of detail. In a state like Punjab, old methods of threshing of wheat have altogether been replaced by the thresher machines and combine harvesters. About 2 lac threshers are used in Punjab during each harvesting season. The number of those who get serious injuries is expected to be around 1000 each year. According to official information given in the Punjab assembly on Sept. 7, 1978, 841 cases of loss of limb or life occured during the previous three years; eight agricultural labourers were killed and 24 cases lost two or more limbs, in others one limb was affected.

Study of Thresher Accidents

People's Health Group, Punjab, has analysed the data of 48 cases of thresher injuries who came for treatment to Rajindra Hospital, Patiala, from January, 1982 to June 1984. Sixry percent of the cases were agricultural labourers while the rest 40 percent were poor and middle peasants. Out of the 28 cases of agricultural labourers 8 were from outside the state while others were Punjabis. Sixty five percent cases were young i.e. below 25 years of age (the youngest being 14 years) 20% were between 25 to 50 years of age while the rest 15% were above 50 years of age. Two cases were around 60 years of age.

Extent and Nature of Injury: Out of 48 cases, six (12.5 percent) involved lower limb injuries while in the rest 42 (87.5 percent), upper limbs were involved. In all cases of lower limb injury the amputation was below the knee. It looks strange how leg injuries could be caused by a thresher machine ? In all these cases the leg was used to push the stuck up fagot of crop when force of the hand was not enough. The strucking up may occur due to defect in the machine or putting in too much crop due to haste. Out of 42 cases in which the upper limb was involved. in 31 (73.881 percent) the limb was right while in 11 (26.19 percent) cases it was left. Amputation was below the elbow in 35 (83.33 percent) cases while it was above the elbow in 7 (16.67 percent) cases.

Causes of Thresher Accidents: None of the threshers being used had any protective device at the time of the accident. all threshers being used in the above cases were cheap models which cost about Rs. 4000/-. In all these cases ISI standards wers grossly violated. It is a known fact that only 10 percent of threshers being used in Punjab come upto the ISI standards. There is a long standing dispute between the industries department of the Punjab govt. and the Thresher Manufacturers Association. The industries departmemt insists on ISI standards while the manufacturer's association tries to bypass these standards under one excuse or the other. Many improved models of threshing machines have become available in the market but have failed to gain popularity because of the high costs. The best model of thresher costs Rs. 40,000/-. In all these improved models the chances of accident are minimal, in addition to the increase in efficiency. Even the cheapest models which were being used in the above quoted cases, can be provided with some protective measures without adding much to the cost. The only drawback of such protective measures is that it reduces efficiency to some extent. Because of this, even when provided at the time of manufacture, they are removed by the land-owners when the threshers are put to use.

Landowners have a tendency to invest least amount of money on the thresher machine because it is to be used only for a few days in a year and that too mostly by the hired labour.

In addition to this major cause of accidents i. e. the defective machines, other factors also contribute significantly-

(i) Every peasant cannot afford to buy a thresher machine alongwith motor or engine. Thus many poor farmers either hire a thesher or share it with their friends and relatives. This increases the quantum of work on each thresher. Thus generating the tendency to run it round the clock.

(ii) Most of the farmers lack space to store the grain and thus are compelled to take it straight from the fields to the market. Fearing the uncertain weather which may damage the unthreshed crops and threshed grains, the farmers have a tendency to finish the threshing work as quickly as possible.

(iii) The govt. usually puts up a time limit for the supply of electricity for threshing purposes. Thus the farmers are compelled to finish the work during that limited period which is possible only by overwork.

(iv) The agricultural workers easily surrender to do overwork because in addition to the psychological pressure of their employer they are anxious to earn for the lean months as the employment is only seasonal one.

Under these circumstances overwork is a universal phenomenon during the harvesting season which is possible only under some sort of intoxication. The most common intoxicant used in such situation is opium which is offered to the labourers by the land owners. It is a well known fact, at least in Punjab that many agricultural labourers become opium addicts during the harvesting seasons. When they become addicted they have to purchase the opium which results in economic and other related consequences affecting directly and indirectly the health of whole of the family. The other intoxicants commonly used are country made liquor, chewing and smoking of tobacoo and poppy husks etc. All these intoxicants, have a tendency of habit formation with their consequent effects. In a nutshell the combination of overwork beyond a physiological limit and intoxication make the worker prone to the accident in an unsafe machine.

In the above 48 cases which were studied by us, 55 percent cases confessed of having resorted to over work ranging from 9 to 40 hours without any rest. However, this percentage was higher 65 percent when calculated for agricultural workers alone. The use of intoxicants was recorded in only 10% of the cases. This was in contrast to the observation by many of our friends who are directly related to agricultural work. The person dealing with such cases in Rajendra Hospital, Patiala told us that the fact of intoxication is usually concealed because of the fear that blame will be put on them and any possible compensation including the free treatment in the hospital may be denied.

The above facts clearly reveal that accidents are not mostly with the use of machinery rather, it is the type of class relationships and mode of production which is responsible for the high prevalence of accidents in the use of farming machinery. Very low incidence of such accidents in China is the best example to contrast backward capitalist mode of India with socialist mode of production.

Further the quality of treatment and rehabilitation will again depend on the class status of the victim because these are purchaseable commodities. Again to contrast the two modes of production, highly advanced reconstructive surgery is available in China to the workers if he or she happens to get such an injury. To think of reconstructive surgery for the Indian workers seems quite foolish. In a nutshell, the chances of having an accident and the amount of final disability depends on the class/caste of the person and the mode of production in that society.

The health hazards associated with agricultural work next to injuries is poisoning due to the use of chemicals for plant protection. In the underdeveloped capitalist countries pesticides are being used on a very large scale, both, for agricultural and public health purpose. The high yielding varieties of seeds which are being used as part of strategy of the green revolution' are highly sucesptible to diseases and to safeguard them highly poisonous chemicals are used. In India in 1983-84 the proposed consumption of various pesticides in the agricultural sector was as follows :

1)	Organochlorine compounds (D.D.T., B.H.C., and Aldrin etc.)	65,035 tonnes
2)	Organophosphorus compounds (like malathion, parathion etc.)	23,000 tonnes
3)	Carbamates	6310 tonnes
4)	Plant origin	120 tonnes
5)	Fumigants	1300 tonnes

The pesticide most commonly being used in India and other backward capitalist (BC.) countries are organochlorine and organophorus compounds which had long been banned in the Western countries where their manufacture originally started. Now, either the factories have been shifted to the BC. countries where they are being run with the collaboration of Western transnational companies or the pesticide is being exported after its manufacture. Two lac of such chemicals are being exported from the US. to the BC. countries.

A recent report of the International Development Research Centre, Ottawa, reveals that there are seven and a half lac cases of acute poisoning with various varieties of pesticides. Half of these are reported from the third world countries out of which one-third are reported from India alone. The number of deaths from poisoning are reported to be 10,000 annually in the third world out of which one-third are from India. The extent of chronic poisoning is so huge that it is very difficult to evaluate its effects. Indians have highest tissue level of DDT in the world i.e. 12.8 to 31.0 parts per million (PPM). The average DDT intake of an Indian is 0.27 mgm/day/person.

In India there is a 5% annual growth rate of pesticide consumption since 1972 with a corresponding increase in the number of cases of poisoning. The people involved in agricultural work are more likely to have acute as well as chronic poisoning than the people at large. Further out of these the agricultural workers are even more prone because the land owner who can afford to purchase pesticides, is usually not involved physically in the plant protection work. The study undertaken in five districts of Gujarat (E. P. W., 1980) also reveals this fact. Farm labourers are worst affected because majority of them are exposed for a longer period due to their continuous contact during spraying operations, and that also without any protective devices. The protective devices are almost invariably not used; firstly, because the manufacturing companies underplay the toxic effects of their product and also are disinterested in the manufacture of protective devices (As quoted in the E. P. W. study only 2 out of the 58 companies studied were manufacturing protective devices); secondly, the whole system being profit oriented and exploitative the rich farmer is not interested in spending for the safety of the agricultural worker, thirdly, because of the fact that the agricultural workers being poorly paid are unable to purchase the protective devices by themselves and lastly because of illiteracy and lack of information the extent of toxic effects are not fully known to the workers.

Very few studies have been conducted on the long term bad effects of pesticides. The Indian Toxicology Research Centre in collaboration with the neurology Department of K. G. Medical college, Lucknow, have conducted some studies. These studies revealed that one-fifth of the farm workers involved in spraying had impaired eyesight following muscular degeneration. Cases of cancer, stunted growth of their children, deformities, blindness, diseases of liver and nervous system have been identified in the cotton growing areas where the use of pesticides is more frequent. A recent study has shown that 73% of these workers had toxic manifestations including cardiovascular and intestinal problems. The agricultural workers of Karnataka, who used to eat fish and crabs from the paddy fields in which they were working and spraying pesticides, were afflicted with severe paralysis and other diseases including what is called "Handigodu Syndrome."

The study of Gujarat quoted earlier had taken the figures of poisoning cases from the civil hospitals of Vadodara and Surat. In all 70 patients of acute poisoning in three years from 1976 to 1978 were studied. All these 70 cases were agricultural workers including two women. None of these workers was provided with any protective device. The hospital admissions are a very poor index of the extent of poisoning. Firstly because all the cases don't reach the hospital, and secondly these are only of acute poisoning which is only a fraction of the total poisoning being done.

There is no legal protection to the victims of such accidents and poisoning cases. Workers Compensation Act does not include these cases under the pretext that the act is only applicable to industrial workers. None of the 48 cases which we studied turned up to obtain any certificate for the purpose of compensation. Similar was the case with the poisoning in Gujarat who were not given any sort of compensation.

We could not trace a case in our study in relation to dermatitis caused by the use of fertilisers, particularly at the time of sowing of paddy, though it is a known fact that handling of fertilizers causes skin diseases which are sometimes so severe that the worker has to abandon the contact with fertilisers.

There is a whole range of morbid conditions resulting from overwork, working in unphysiological postures, and the associated drug at use. With the introduction of mechanisation in agriculture and strengthening of its bonds with the market has increased the intensity of exploitation of labourers. The intensity of extraction of surplus labour has increased many folds which in the given set of class relationships is bound to increase the alienation of the workers because psychological alienation is in direct proportion to the extent of alienation of labour power. The usual expressions of psychological alienation i.e. psychosomatic disorders, psychological diseases, use of intoxicants and crimes etc. are bound to increase. Though no study evaluating these effects could be traced, yet one can easily feel their increasing trends. The rise in all these disorders in society, including rural, is clearly visible. Though these disorders are not confined to the agricultural workers, the total quantum of morbidity in this context is very obviously more on them than the other relatively privileged classes.

Because of the above facts combined with the changing social pattern and breaking down of old values, the use of drug intoxication is on the rise. The effect of those intoxications is bound to be worse on agricultural labourers because of their

(Contd. on page 140)

Marxist View of Health & Medicine : A Rejoinder

Bharat Patankar and Jogin Sen Gupta

In its first issue SHR rightly carries articles on historical and general perspectives. We think it is necessary to give an immediate response to the perspective which comes out in this issue of SHR (1 : 1)

In his review of *A Cultural Critique of Modern Medicine* Anant Phadke writes, "John Ehrenreich first traces the historical and political origins of the 'cultural critique' of modern medicine. Ehrenreich alleges that the political economic critique concentrates its fire on the inequitable distribution of health services, on the problems of organisation of medical care and is not much concerned with the nature of medicine itself. Ehrenreich is not entirely correct in his analysis. There are marxist analysts who analyse the political economy of health not primarily from the standpoint of distribution of medical services."

While it is true that "there are" marxist analysts who take a different approach, the point is that the vast majority of them take the viewpoint critiqued by Ehrenreich. In India, for example, we must ask, among thousands of marxist doctors, political economists and cultural workers, what sort of debates on the cultural and political aspects of medicine we have had up to now?

Howard Waitzkin's article is revealing as it purports to give a detailed and researched account, with 260 references, of marxist analyses in the field of health care covering about 150 years. It is an excellent example of Ehrenreich's claim.

Waitzkin starts from Engels' *The Condition of the Working Class in England.* In this, "the first major marxist study of health care... Engels traced such diseases...to inadequate housing, malnutrition,contaminated water supply and overcrowding .. This treatment was to have a profound effect on the emergence of social medicine." With this, he makes his views about "health" and "health care" explicit at the outset. Can causes and removal of "poverty diseases" be the central problematic of Marxism in "health care"? (Even Marx and Engels were less confused about their target - not poverty but exploitation and oppression). In developing countries, "poverty diseases" still play a huge role. But what is the situation in Waitzkin's own country and the rest of the developed world? Today, the advanced bourgeoisie and the modern state have almost eliminated "poverty diseases", as Waitzkin also observes later. Poverty, unplanned industrialisation and to an extent ecological imbalance as the causes of "ill health" are not only propagated by established sciences but are incorporated in some form or other in the legal provisions of the bourgeois states, e.g. OSHA (Occupational Safety and Health Act) in the U.S.A. But this transforming of sick slaves of capital and the state into healthy ones has not weakened the system at all; it has led to strengthening its tentacles of exploitation and control. And, did the world have to wait until Engels to learn that bad living conditions lead to many diseases? Did these start with capitalist industrialisation? These stated far earlier—from the time of the city-state-civilisations. Tribal communities were much healthier. The sanitation engineers of Mohenjodaro surely had a clear understanding, of the problem.

With such a traditionally defined view of disease, the central aspects related to health in both the "developed" and "developing" world—ecological devastation, poisoning of the environment, alienated relations between humans and nature, militarism that threatens the survival of all life, sexism and racism, large-scale cultural-psychological perversions, and destruction of human relations — are ignored completely by Waitzkin. Realisation of such factors has raised basic questions for Marxists in the "developed" world : such as, can one solve such problems simply by taking over the existing poisonous forces of production? And, given massive cultural-ideological-psychological mutilations produced by the system, can the "working class take over the state"? Also, arethese problems simply due to the capitalist mode of production, as Waitzkin's approach implies, or are they the end result of an accumulated chain of patriarchal, statist and class societies?

Waitzkin gives great emphasis to the nature of exploitation in the capitalist production process in terms of surplus value and the class structure defined by that. He takes this as Marx's approach. To do this is a very limited cognisance of the analysis of the capitalist system given by Marx himself. In *Capital* Marx deals with many other aspects like alienation/estrangement, devastation of natural resources, destruction of cycles of nature etc. The article also ignores recent studies of the

nature of the internal structures of industries and of their production including their effects. This narrow approach forces the author in to the trap of emphasising control of the means of production and poverty, which cannot lead to any alternate conception of illness and health care differing from the established concept. The most serious effect of this is the complete disregard of relation between questions of health and the oppression of women, minorities, lower castes and others. In the author's own country there are countless examples of women's groups and minority groups and alternate-psychiatry groups raising these issues. In this situation ignoring this challenge is an inexcusable mistake. For the last some years communist parties and marxists in general have been facing many difficulties in trying to deal with such issues within the framework of a narrow approach to "surplus value and class exploitation." Many marxist studies have come up which are trying to develop a new approach. But the author does not confront this issue. He talks about women at one point. "Historically, women's use of health facilities and the attitudes of medical practitioners towards women's health problems have depended largely on women's class position" (1,1) ignoring the specific oppression of women even within the working class. Some words mentioning "housewives' problems" cannot wash out this serious error. The fact is that in the USA it is not working class struggles in the economic sense that have transformed the meaning of "health", but the anti-sexist, anti-racist movements and those in the area of ecology and militarism right up to the tiny but significant issues raised by alternate psychiatry, gay and other movements that have forced us to re-examine our concept of "health".

The author's mention of his view about revolution at the end of the article expresses in a nutshell, his imprisonment in a mechanical and outdated approach towards alternate health. He writes "Gaining control of the state through a revolutionary party remains a central strategic problem for activists struggling for the advent of socialism." (1 : 1) Among other things, this conception becomes dangerous for the emergence of any perspective of alternate health. First of all, it is a serious distortion to give the reference of Lenin for this statement. Whatever may have followed the October revolution, Lenin did not have a conception of "gaining control of the state through a revolutionary party". His was a conception of *smashing* the old state and establishing *Soviet power* which was also supposed to go on withering away. This approach at least implies peoples' control and gradual decentralisation and dissolution of centralised power over the heads of the people. Such a view has very positive implications for alternate health practices in relation with the emergence of the self-management of health by the people themselves. At the same time, with the experiences of the post-revolutionary societies it is evident by now that a statist approach gives rise only to a new but still oppressive system and maintains the powerlessness of the working masses. At one point the author touches the problem briefly where he disusses the USSR in relation to the class position of medical professionals. But mainly he poses increasing state management of health as a progressive development by showing how capitalists oppose it or how private practice interests still manage to exploit it. This cannot explain the existence of severe health problems for the mass of the population in countries like India where the state sector is predominant in health, or even in the Soviet Union, China and other such countries where frightening things like devastating ecological imbalances, the masses spread of alcoholism and so on, continue to occur.

The party-controlled state and the conception of revolution which emerges out of the concrete practices of post-revolutionary societies can create nothing but a society in which health-related major ecologjcal problems of capitalist industrialisation and agricultural production continue to exist. It cannot create a health system which is not alienated from peoples' creativity and the natural balances between humans and nature. Of course, from Waitzkin's view of health care specialist doctors plan rationally, the state implements it. If health is lack of some illnesses and mortality/morbidity rates are the indicator, there seems to be no problem. But in our conception, illness and health care are a mode in the relation between people. This can be liberative or oppressive. Liberative, when it is an aspect of a movement against distortions of our mind and for social liberation. Health work can grow in terms of increased mutual and community care when it becomes a means of building up the solidarity, humanity and autonomy of people in communities, with technology and specialised knowledge shaped by and helping the control of these processes. Conversely, the state may soak up this possibility of mutual help and self-management and strengthen the top-down, specialist apparatus and power over the people. Such a way strengthens the mode of life based on "Give power to the leadership/state and they will look after you." Waitzkin misses the fact that the more "efficiently"

and "successfully" this mode functions, in reducing mortality and morbidity, the more is its success in empowering the state at the cost of the people.

Illusions created by the "public-private contradiction" have made many communist parties and otaer marxists think that the growth of the state sector is something progressive and going nearer to socialism. But the *health system* will not radically change to become a liberative process if the new arrangement only subtracts the bourgeoisie and replaces it with experts and bureaucrats while organising a better distribution of the existing type of facilities. We have to break from the prevalent concept of health forced upon us by centuries of the health establishment and society — and to understand a health system as itself a process of liberation.

Finally, after defining the "central strategic problem for activists," Waitzkin concludes by describing what they are doing. But this can be extremely misleading, for of the three trends he more or less classifies as those advocating a "vanguard party", a "mass party" or "counterhegemonic" work, only a very small minority hold the mechanical view of taking control of the state which he puts forward in the article. To say that "Party building is now taking place throughout the United States (1.1.)" is an inaccurate, to say it most kindly, depiction of the innumerable mass movements the US has seen.

If we look back at Waitzkin's own bibliography of 260 references, there is hardly any marxist critique of health before 1970 in the USA. The reason seems to be that it was the struggles of blacks, women youth and others that transformed the earlier sterile attitudes towards health and stirred them up. It is sad that Waitzkin, instead of starting from the reality of the movements, reverses this process by trying to fit the creative activism of the people into the "work of Party builders" and into such an authoritarian and narrow concept of Marxism. In the end, his type of "marxist view" raises the question, what was Marx's view? Marx vigorously supported movements against exploitation and oppression and tried to learn from them. In his openness to learn from rebellions he was ready to throw away much of his earlier views. This, and not narrow theoretical preconceptions, we think, should be the "marxist view."

Need for Analtyical Rigour

Imrana Quadeer

SHR's effort to provide a platform for discussions and interaction between activists in the field of health and its focus on the process of distilling the truth from various trends within the marxist movement is most welcome. However, the fact that health and medicine cannot be separated from the problems of the wider social order, underlines the dilemma that no serious analysts of health and medicine in India can afford to take for granted the issues within this wider social order. A theory of health and medicine is not possible in isolation. Those who try to build such a theory would be required to develop an analysis of society as well. SHR has circumvented the problem by leaving this task to other forums and have presumed that readers will either know the debates on these issues or will accept the views that contributors present. An easy way out perhaps, but not one that is conducive to constructive debate on either the specific theory of radical health action or general theory of radical political action. For example, when we talk of "political economy of health", "articulation of medicine within a mode of production" or "class structure in health system" without specifying our understanding of the terms used, we not only fail to communicate but often create confusion.

It seems to me that a debate concentrating on health and medicine alone, however rigorous, tends to treat these generel concepts superficially. Thereby, hampering the very purpose that it set for itself, that is, understanding the relationship between health and society. I would plead therefore, that even if SHR is interested in a very restricted readership of the aware converts, it still needs to handle the wider social system with much greater rigour. However, if SHR is interested in a readership, of doctors and other health workers who were attracted to marxism because in it we found a better approach to handle our own contradictions and for relating ourselves to the wider society, then SHR's policy becomes a major handicap. For us, the study of health, medicine and health services in India has not only been instrumental in deciding our professional roles but it is also a tool for understanding the society we live in. SHR does not seem to be interested in that window.

I would infact argue that this neglect leads SHR into an uncritical acceptance of certain general formulations which might sound very radical but which do not stand the test of scrutiny. The mere quantum of the so-called marxist analysis of health, done in the west has so impressed us that we have literally lifted their formulations and transplanted them on the Indian scene, without even thinking whether they are applicable. Further, in our hurry to fill in the gaps in our knowledge, we have concentrated on theory of health and medicine. That theory however, has been sought by filling the accepted theoretical constructs with Indian data and developments rather than beginning with health and health services itself to test the assumptions as well as the theoretical constructs. Such an approach creates many conceptual and merhodological problems. Another weakness has been our definitions and terms and the lack of empirical analysis and date base.

Let me take the first issue of SHR to illustrate my points. I would treat. Amar and Padma's[1] as the central paper and touch upon others when needed.

The Use of Concepts

An important assumption of the analytical framework is that mode of production in a society determines directly its health care as well as patterns of illness but it has never been proved and often negated. According to the authors, the socioeconomic structure even after independence remained more or less intact, the bourgeoisie dominated the scene and till today capitalism remains the dominant mode of production. If that be so, then there should be no change in the basic pattern of modern medicine. The authors in fact demonstrate to the contrary that there has been a major shift from "scientific medicine" to "community medicine." Furthermore, it is argued that the major factor which influenced changes in health care were the notion of welfare state, planned development, pressures of world capital class conflicts and project optimisation. It appears then that :

(a) the period covered in the main article is not sufficient to use the analytical category of mode of production.

(b) within a mode of production also, patterns of health care may vary depending upon the prevailing social relations.

The other theoretical construct that is assumed as proven and asserted vigorously to make a point instead of empirical data, is the concept of health as labour power. On this is based the understanding that input in health care by the state has an economic basis because it is necessary in the creation of surplus value. Even the fact that in India 90 percent of the industries belong to the unorganised sectors whose workers are provided no facilities for health care, agricultural producers who contribute 45-50 percent to the GNP have little access to health services and the existing health care facilities of the country are utilised by the elite and the middle class not the labouring classes has not provoked us. Could it be that the existence of a large reserve of surplus labour and the nature of technology combined with organisational forms like "contract labour" and "casual labour" devalue this concept in the Indian setting ?

Related to this question is yet another formulation which needs to be looked into and that is "commodification of health care in capitalism". The authors argue, "it is immaterial whether the surplus value is realised directly through the productive activities in the clinic and hospitals owned by the capitalist or indirectly through the provision of services by the state ....". In either case, the maintenance of productive capacity of labour is central in the creation of surplus value. It is assumed then that in commodity "health service", the surplus is not generated in the process of commodity production but outside it ! A strange view of Marx's "surplus value". The confusion has perhaps arisen because we do not make the distinction between the 'service' and 'material' outputs (like drugs, instruments, equipment etc) of the health industry. The later like any other commodity, generates surplus value and therefore profits. In the service component of the output, things are quite different. The surplus in clinics and hospitals or any other medical care institution comes from the exploitation of the health workers who are paid wages. They are paid for their subsistence (socially determined) whether they are in a private hospital or a public hospital. It is this that must be understood to appreciate why in capitalism, welfare is not an economic proposition. The services though in the name of the poor and the labouring go to the unproductive sections of population and hence in reality, there is relatively little investment in the labour power of the industrial or agricultural workers. At the same time the socially determined subsistence for doctors — the pillars of health services — are undesirably high.

It must also be realised that a practitioner even in a capitalist formation continues to provide service (commodity) without creating any surplus value for he is charging for his hours of labour and not

his subsistence. That is why a private practitioner earns even more than a doctor who is paid wages even though he may be of the same status. It appears then that the production of surplus value is not as intimately associated with profits in the provision of health services as it is assumed. Hence the economic reason for the state to run health services becomes less tenable.

Yet another formulation that needs to be corrected is that "modern medicine and hospital systems reproduce the social structure of bourgeois society." I would think that the two may replicate or mirror bourgeois relations or structures but can not reproduce it. If they could, then, the sheer presence of hospitals and modern medicine in Russia, China, Cuba, and Vietnam would be a threat to their present social systems. A proposition which is just as ridiculous as it sounds. Also in Dalli Rajhara, the hospital workers would not be able to practice modern medicine and at the same time attempt to evolve a new set of social relations. In other words there is a need to realise that a system based on division of labour and controlled by a collective is different from one where division of labour as well as ownership is a function of class.

Need for analytical rigour

The above discussion brings us to the question of class analysis and its relevance for the understanding of "political economy of health.' At this point I would not go into the question what this term denotes but assume that the effort is to see how class configurations influence patterns of health care. To approach this question, the authours go in great details of the industrial and agricultural growth pattern and the emergence of various classes. In tracing the evolution of the peasantry though, no mention is made of the rich peasants' role in the green revolution areas as well as those where green revolution did not happen. We are told that the marginal and small peasants did well in both these areas. This is unconvincing as it neither explains the increasing numbers below the poverty line since 50's nor does it explain the process of proletarianisation and pauperisation of the peasantry. Secondly, though the emergence of these classes is traced, the differences in health needs of these classes are never discussed. We are at a loss then to see if that too played any role in shaping the health services. Thirdly, in their attempt to establish causalty between health service development and changing balance of class alliances and class conflicts, they make some weak propositions and offer scant data to substantiate their arguments.

(i) It is argued that bourgeois radicalism "can best be viewed as concessions gained by working class militancy". Hence all expansion in services is projected as a result of protest and struggle. We therefore fail to make the crucial distinction between a conscious demand (or protest) for health and socio-economic unrest or instability which is often appeased by offers of bonuses and concessions in welfare services. In the former the ruling classes are forced to give in, in the latter they provide health services by choice and refuse what is really needed. Apart from this strategy of appeasment, the ruling classes also provide services because of their own direct interests economic, political, ideological [2] and physical. Also they use both preventive and curative services not just curative as the authors tend to believe. It is then necessary that to establish that expansion of services ("implementation of various reports") was a result of struggle, we locate those struggles specifically and show that provision of health services was one of their demands.

(ii) In their analysis of the 70s, they say that the emphasis on rural inputs and family planning was an attempt to postpone 'the crisis'. Without identifying the full nature of the crisis (a part of which was industrial stagnation) they further argue that the rationale of the Indian bourgeoisie in adopting a massive family planning (FP) drive was a means of controlling labour supply to suit the expansion of more capital intensive modern industries. Firstly how a capital intensive expansion of industry can be possible when there is a glut and how is it going to remove industrial stagnation or the crisis is not indicated. Secondly, despite the fact that they mention expanding numbers of unemployed people, increasing population and imperialist pressure as factors influencing acceptance of F.P.P, why they consider "controlling labour supply as "the rationale" of the bourgeoise" is never clarified.

The questions regarding the nature and resolution of the crisis can only be answered by taking up the nature of the state and the problems of surplus accumulation in India. I will not go into them, but to analyse the rationale of F.P.P. we should have certainly made some efforts. The facts are,

a) that the emphasis on F.P.P. came in the 3rd plan itself when the investments in F.P rose from 30 million to 26.97 million rupees.

b) that though it is true that in 70's the population growth rate was high, it is not adequate to

say that "the population went on rising, hence the labour force continued to expand". The rates of expansion of these two are not equal. Since the labour force increases only by new enterants into it (young people) who were born at least 10 years back. Therefore, labour force increases at a rate which is equal to growth rates of population 10 years back which in our case was much lower (22.2 in, 70s, 18.9 in, 60s and 12.5 in, 50s).

It appears then that the control of numbers of labour force alone could not be the main rationale for accepting the F.P.P One expected that instead of treating F.P.P as a welfare programme, its real nature would be exposed (where compulsion and force made their appearance as early as 1966-67). and its class orientation made explicit. F.P-P neither came as a concession to the growing political clout of the middle farmers nor it ever lost its ideological value for the classes for which it was meant. That is why it still survives in almost the same form as it did a decade ago.

(iii) Throughout it is argued that the model of 'scientific" medicine (with all its social relations and economic possibilities) was suited to the Indian bourgeoisie, and therefore it expanded. The working class continued to extract more and more through its struggles (or so we would like to believe) and the rise of the peasantry created additional pressures Suddenly however, we are told that by the second half of the, 70s this specific model, "no longer performed either this ideological role or achieved their socio-political objectives". In fact, "it was no longer a good economic option". Hence a shift in strategy by the bourgeoisie from "scientific" medicine to "community" medicine. Why all of a sudden welfarism lost its value why health services started eating into the surplus and why they no longer performed their legitimising role, are questions left unanswered.

I suspect that the idea of failure of the western model is located in our minds and is strengthened by the "radical bourgeois documents" which are forever crying their hearts out. Our susceptibility leads us into accepting their logic rather than exploring the truth. Let us answer the following questions. For which classes, hospitals and the PHC complex are no more the answers to their health problem? Even when they get nothing out of the government health institutions, do they not go to the private clinics of the same doctors for better scientific medicine? Given the choice will people prefer a community health worker or a doctor? The answers tell us that in India as yet, modern medicine faces no crisis. The crisis is of the bourgeoisie, who even if they wanted, can not provide it to the people and therefore must create blinkers. The authors have themselves shown that the present policy paper is nothing but an effort at streamlining health services in a way that the old model remains its core and is assisted by the so called "community medicine" component to create profits, provide political legitimisation an ideological domination. Secondly, the argument that "there had not been any large scale improvements in health indicators in the past years" is also not adequate to locate the crisis of health care in late 70s. These indicators are neither indicative of health status of classes nor do they show overall worsening (death rates for '50s, 60s &' 70s were 22.8, 19.0 and 14.8).

While Amar and Padma make one think about all these questions, Waitzkin in his article creates much confusion on the very subject of class analysis of medicine. Having located the structural source of exploitation in the process of surplus production, he introduces the notion of "persistence or reappearance of class structure usually based on expertise and professionalism in countries where social revolutions have taken place", without, even going into the definition of 'class' used by Bettelheim and Ehrenreich. At the same time he takes great pains to tell us about Alford's research which talks of "interest group" analysis without any comments on the value of this analytical category vis-a-vis 'classes' understood by marxists.

Waitzkin not only indulges in such 'innocent" confusions but also misleads. For example, he introduces the concept of "social imperialism of the USSR" and attributes it to Navarro who in fact though critical of the "party domination" and "managerialism" in Soviet Union, has never used this concept. In the book quoted by Waitzkin, Navarro has actually argued against the theory of convergence and criticised those Western scholars who project managers, administrators, and technocrats as a "new class" of controllers of the system. He underlines the fact that supermacy of the political party over these groups is distinct in the Russian society.

Need for better empirical basis

Yet another methodological point that needs to be repeated is the need to validate arguments and proposition. The practice of making conjectures which are not substantiated must be avoided at all

costs. For example, when we say that "by the 60 s increasing urbanisation with a 40 percent increase of urban population, inadequate housing and living conditions, low availability of food and impoverishment and unemployment has pushed up disease incidence, "we have neither data nor logic on our side. Disease incidence rates or morbidity data for the country simply don't exist and logic says that if people are migrating from villages to urban areas they must have good reason to do so. Will they move from better into the worse ? Similarly, whie talking of the early '50s, it is said, "recent series of famine and draught, increased exploitation of wars, further deterioration of the abysmal public health services the post partition exodus had resulted in a labour force which obviously could not contribute its best in terms of productivity". Here again the emphasis on health which seems so obvious to the authors, is never really validated. Unless we explore all the factors which were responsible for the disruption of industrial production or for its low performance, (investments, technology, social situation) to isolate poor health of the worker is to blame him for non-performance.

Use of dialectical approach

In outlining the political econmy of health, the authors repeatedly use the terms "western medicine" "scientific medicine" "allopathic medicine" and "modern allopathic medicine" interchangeably and then criticise scientific medicine because it developed in a capitalist setting and was moulded by it. It becomes difficult to judge therefore, whether they are critical of the allopathic system's body of knowledge (of which preventive medicine is a part) or its organisation in a capitalist setting or both. Specially because, despite their ideological criticisms, they do not deny that the increase in the number of health personnel and institutions was necessary or useful[2]. The problem is further confounded when talking about the '50s they claim, "if the recommendations of Chopra Committee were implemented at that time they would have resulted in a drastically different system of medicine". Firstly, why a system of medicine that developed in a feudal society would offer a better alternative to the set of social relations imbued in "scientific medicine" is not argued. Secondly, even at the level of ideology why ayurveda as practised in the British period was less class-based, sex-biased and individualistic than allopathy (not to mention its dependence on obscurantism and mystification) is never explained and thirdly, why indigenous medicine would not be just as easily ammenable to capitalist commodity production and absorption in the capitalist system like other feudal institutions is never clarified.

If we agree that the indigenous systems were more widespread and culturally more suited then, we should also grant the bourgeoisie the intelligence to see the profits of a wider market and easy profits of indigenous medicine. However, our intense dislike of the bourgeoisie never really allows us to explore what could have been their other reasons for rejecting indigenous medicines[4]. The problem is, lack of appreciation of the dialectical nature of medicine (allopathic or ayurvedic) which alone can help us to trace the roots of an alternative medical science and technology and an alternative basis for organisation of medical care. Waitzkin does mention a different kind of 'modern medicine' which was practiced by Virchow. However, he does not explore the reasons why the germ theory instead of strengthening actually undermined both epidemiology and public health and what role these disciplines played in the 18th and 19th century.

A much discussed subject is reformist and non-reformist reforms. Every one seems to agree that the former is bad and the latter good because non-reformist reform alone can lead to revolution while the former only strengthens the system. What we tend to forget is that implimentation of reforms is a tool for survial for the bourgeoisie and not the function of a revolutionary movement. The latter extracts reforms, struggles for it but does not implement it. Lessons from history teach us that the essence of a reform is in the change that it introduces in the structure of the bourgeois society and not the material benefits (though they are very important at that point of time). Reform has its own dialectics, it may diffuse a struggle but it also heightens the contradictions within the bourgeois structure. In other words, it sows the seed of change in the objective reality of social structure and not in the subjective reality of working class consciousness. That is the role of revolutionaries.

To say that experiments which help leaders of a working class movement in increasing class consciousness is reform (even if it is called radical) or to claim unimplemented drafts of the opposition as radical reforms (they are demands for reform not reform) is not only wrong but misleading. Misleading because it tends to divert attention from the essence of reform (structural change) and confuses it with either "mobilisation of political support" as claimed by Waitzkin or with strengthening of a union as Binayak and Ilina do. They ignore the fact

that a politicalised union as strong as Chhattisgarh Mukti Morcha is not making provision of health services a part of its demands and extracting it out of the management, instead, it is providing these out of the wage of workers (same as the bourgeoisie) ! In doing so it leaves the health structure created by the bourgeosie intact and therefore is not struggling or extracting reforms at all. The step might be radical but there certainly are no reforms.

The issue whether a revolutionary union is justified in running its own hospitals, schools and industries is a separate issue all together and I won't go into it. But I would like to point out that Binayak and Ilina tend to confuse "reforms" with "reformism". The former is a visible change in the objective reality, the later an approach, a subjective component of ones ideology. A reformist (whose ideology may be reformism) may attempt to "suppress emerging class antagonisms" through reforms and might "need to derive strength" from wherever but the reform is innate (it cannot be vitally conscious of itself) and is the seed of change for it has the potential of hightening contradictions and weakening the very system which the reformist tries to save.

Unless we appreciate this dialectical nature of reform (and all other phenomenon) we would never grasp the meaning of the quotes that we quote. We would continue to make the mistake of rejecting things in toto — whether it is "text book epidemiology" or " operation research rooted in capitalist culture" and not apprehend the elements of a revolutionary alternative which exist not outside but within the bourgeois society.

If we agree that the basic assumptions which we started need to be reexamined in our given context, then we might also agree that perhaps the way to make a beginning is to attempt detailed analysis of the contradictions within the health system and their manifestations. For example a study of contradictions in health care policy and practice (one professes service to all, the other provides for some, one eulogises free medical care the other promotes private service, one emphasises preventive the other curative medicine and promotes technology to solve social problems) will help us locate the relevance of what was mentioned in passing in the main article as "constraints" to bourgeois "options". These "constraints" of foreign capital intervention, class pressures and class conflicts and a policy of welfarism in absence of adequate capital accumulation are actually the links between health planning and the wider socio-political and economic frame of the society. Links which need to be further studied with references to health as well as the Indian social formation.

The challenge that SHR faces is to build up a theory rooted in Indian reality. For this four things are necessary. One, that the frame-work that we use must be first critically evaluated. Second, that our analysis must concentrate on trends emerging from the available information and data on health. Third, we must attempt at collecting data where it is necessary. Lastly, if our study demands an exploration of the wider social system then that must be attempted. Towards this I join you in solidarity.

Notes

1. I hope they would not mind my use of first names. My effort is not to score points but to share with them what I think and first names make it easier.
2. Liberalism is very much a part of bourgeois ideology which reflects the positive forces within it.
3. Even if they really consider it futile then their rejection of modern medicine is clear and my argument does not change.
4. I do not mean that indigenous medicine is to be rejected. My plea is that the same analytical framework should be used for indigenous medicine if is to be compared with modern medicine.

WORK HAZARDS : WHAT CAN WORKERS DO ?

The best devices for detecting hazards in your workplace :

Nose : To smell foul odours as a tip off to hazards and to stick where management says it doesn't belong !
Ears : To listen to the complaints of the workers
Eyes : To spot hazards and poor work conditions
Mouth : To argue the worker's point of view
Guts : To have a gut level reaction about what's right and what's wrong and to have the strength to stand up and get the hazards corrected
Brain : To be imaginitive in building the union's safety programme

'Death on the Job'

a d'mello

Death on the Job — Occupational health and safety struggles in the USA. Daniel M. Bergman, Monthly Review Press, New York, 1978, 2 pp. 12.95 dollars

The movement for awareness about occupational health and safety is still in its infancy in India. Trade union activists and social workers involved in welfare projects for industrial workers will be mollified by knowing that even in what is probably one of the most unionised countries in the world, the movement has still not caught on in a big way. Occupational health and safety struggles have still a long way to go before they make a dent in governmental and industrial circles.

Daniel M. Berman in his book "Death on the Job", which deals with occupational health and safety struggles in the USA, states that despite the passage of the 1970 Occupational Safety and Health Act (OSHA) as a consequence of widespread social discontent in the 1960's, major changes still remain to be achieved. "Violence against the spirits and bodies of workers continues".

The author states that business has been forced to deal with issues of occupational safety and health under two different sets of conditions, during war imposed labour shortages and during periods of severe social upheaval. When labour is extremely scarce, employers worry about preserving the labour they control by making the work more attractive. During times of severe social unrest workers demand better conditions. In both cases business tries to jump ahead of the workers and create institutions which define the problems of health and safety in non-threatening ways and take the sting out of the workers unrest. Berman speculates that perhaps the new occupational health and safety movement arose during an epoch that combined labour shortages and widespread protest against the unpopular war in Vietnam.

Tracing the history of the movement, the book deals with the manner in which the early twentieth century US corporations responded to concern about work accidents by setting up a business controlled compensation safety apparatus which held down compensation costs and did little to improve working conditions. This apparatus was able to exclude the issue of occupational health and safety from open debate until the late 1960's through its control of research, education, workers compensation, governmental appointments and by creating the public impression that health problems in the workplace were non-existent. As a result, the pain and bloodshed and nearly all the money for the costs of work-related diseases and injuries are still borne by workers and their families, and the public at large. That way, say's Berman, its cheaper for the industry.

With the exception of the United Mine Workers' activities and sporadic local uprisings, unions have been seriously involved in health and safety only in the last decade since they mobilised to pass the Occupational Safety and Health Act of 1970. The OSHA law says Berman, was made possible because of a tight labour market, worker dissatisfaction, the new environmental consciousness, the aid of progressive professionals and a climate of social unrest in the USA.

Berman, while giving reasons for the lax safety standards in the industrial sector, pinpoints the political-economic context of industrial safety at the turn of the century. The rapid industrialisation of the United States produced a multitude of new dangers for workers. Big business, unable to control ruinous competition and confronting a militant working class and a growing socialist movement, sought the aid of the federal government. The fruits of fabulous productivity increases were gradually concentrated in fewer hands, symbolised in 1901 by the organisation of the United States Steel Corporation, the nation's first billion dollar business. As a result the competitive sector i.e. independent farmers and small businesses, were squeezed by the relentless advance of big business allied to the banks. Smaller manufacturers, unable to raise prices easily violently fought unionisation, while few leaders from the monoply sector began to devise sophisticated methods to forestall unionisation through token welfare policies.

Meanwhile, by the end of the nineteenth century' large corporations and sweatshops began employing millions of hopeful immigrants in dirty jobs that still paid better than peasent work in Southern and Eastern Europe. Giant corporations, led by the railroads, usually learned to use regulatory commissions

to consolidate their control of markets and public opinion. The Congress and the Presidency were finally secured for big business by the elections of William Mokinley in 1896 over the ragtag Democratic-Populist coalition. Labour, beaten badly in a series of strikes in the late 1880's was on ascendancy in 1900 but unions made little progress in organising the new mass-production industries. A 1904 report in the labour press estimated that 27,000 workers were killed on the job each year, and a 1907 Bureau of Labour report put the annual death toll at 15,000 to 17 000 of 26 million male workers. Women's work was low paid and sometimes more dangerous.

Even though there were unions fighting the issue of workers compensation the odds were stacked against the workers right from the beginning. By 1908 workers' compensation and job accidents had become major items on corporate agendas. Existing common law doctrines made it impossible for workers to collect damages for injuries suffered on the job because the worker had to prove the employer was at fault. This was particularly difficult for severely injured workers to collect damages for injuries suffered or for workers killed on the job whose relatives had to depend on the testimony of supervisors and co-workers who could be bought under employer pressure.

Though workers' compensation became a major theme by 1920 occupational diseases however never merited much attention in either the model or actual laws, and so they remained as they were till the late 1960's. Till then the workers compensation systems and the unenforced industrial safety laws proved to be everything their corporate sponsors had hoped for. Both management and insurance interests benefited by the shift from chancy jury trials to administrative agencies whose employees could be bought off or coopted. Physicians were hired to deal with work injuries and to represent employers within the compensation bureaucracy, creating that peculiar institutional "ghetto" called industrial medicine.

Berman gives interesting details on what methods the big corporations adopted when they were dealing with workers who were organised. One such example is the case of the Amalgmated Association of Iron, Steel and Tin Workers, a craft union, enrolling only skilled workers. The Amalgmated Association reached its height of power in the late 1890's and the Homestead, Pennsylvania, mill was its biggest locale. It was also the biggest mill of Carnegie Steel, the largest US steelmaker.

"At Homestead about 25 per cent of the 4,000 workers were in the union, where they controlled all aspects of production. This situation was unsatisfactory to Carnegie Steel for two reasons : according to the contract, workers got a constant share of the increasing sales of the mill, and they had the power to prevent the introduction of labour-saving technology if it did not suit them. Carnegie resolved to break the labour in a definitive test of strength, Before the contract expired in 1982, the management built a three mile long fence around the plant with shoulder level rifle holes every 25 feet. The workers were told that after June 24 the Carnegie would deal with them only as individuals. On July 2 most unionised workers were locked out. The union backed by all the workers responded by shutting down the mill renting a steam boat to patrol the Monoghaela river, and orgainsing the whole town for resistance. When bargeloads of three hundred armed Pinkerton men were brought to force the mill open and bring in scabs, an open gun battle resulted, sixteen were killed, including seven Pinkerton agents and the rest of the invaders surrendered to the workers and their families. But after a four month strike Carnegie won the Homestead war with the help of the Pennsylvania militia and the plant resumed production without a union. Loss of its most important outpost was the beginning of a rapid decline for the Association. After a disastrous strike in 1902, the union was completely uprooted from the steel industry".

In 1910, U.S. Steel inaugurated the Voluntary Accident Relief Plan, based on models developed in Bismarkian Germany by a conservative capitalist class under challenge from the fastest growing socialist movement in Europe. The programme, soon superceded by the state workers compensation laws, was the first of its kind in the USA and paid workers or their families fixed amounts for job-related injuries causing disability and death. The plan for all its purported liberality stated explicity : "No relief will be paid to any employee or his family if suit is brought against the company' and workers who received relief were required to sign away any further rights to sue U.S. steel. This became the model for the rest of the USA.

The compensation safety apparatus is the complex of mostly private, corporate-dominated organisations which are concerned with compensation, workplace inspection, standard-setting, research, and education in occupational health and safety. It is called the compensation-safety apparatus because it emphasises compensation over prevention

and safety over health in its activities. It is an apparatus because it has executed the policies of only business and insurance interests for decades as the organised constituency in occupational safety and health. Only in the last ten years has its dominance been challenged by workers, unions and their progressive allies.

Serious attack on the compensation-safety apparatus began in the late 1960's in the coal mines, over issues of black lung. The issue was taken up by workers in industries all over the USA. President Nixon finally signed the Occupational Safety Health Act of 1970. The law, says Berman, promises more than it delivers. However from this step onward things begin to change and various unions take up the issue of occupational health on a larger scale. Berman goes into details about the conditions of work in the oil, chemical, rubber and atomic industries and the way in which their respective unions tackle the problem of occupational safety. Interesting details emerge of the lifestyles of some of the American labour leaders. Referring to the largest union in the USA the "Teamsters" Berman states that "Top Teamster officials live royally on the members fees. Five jet aircraft and two turboprops worth over 13 million, dollars and costing over 2 million dollars annually, fly the top leadership to its missions. Frank E. Fitssimmons, general president, recieves an annual salary of 156,000 dollars and a host of other benefits, and Harold Friedman, president of Bakers Local 19, a Cleveland local associated with Teamsters, recieved the astonishing total of 352,330 dollars from his various union jobs in 1976. Compared with their leaders lifestyle the Teamsters efforts in health and safety are decidedly meagre".

There is also a chapter on the future politics of working conditions and Berman says that with the coming of more and more automation the future worker will suffer more from stress hazards as compared with the worker of today. The book contains useful tables and statistical information about the compensation apparatus in the USA.

(Contd. from page 129)

already poor health due to the vicious cycle of disease and environment as already pointed out.

There are certain morbid conditions which are associated with the unphysiological posture while doing agricultural work, for examples while sowing paddy one has to stoop for hours together which ersults in backache. Postures during harvesting of wheat and rice are also uncomfortable and unphysiological giving rise to a variety of joint problems.

Lastly, there is a miscellaneous group of disorders to which agricultural workers are much more prone than the people at large. Sun stroke and heat stroke are quite common because of prolonged hours of work in the scorching heat. Ailments of the eye are also more common because of the harmful sun rays and dust falling on the unprotected eyes. Injuries to the eyes are also quite common because of the same reason. Agricultural workers are quite familiar with the bites of poisonous animals like snakes and scorpions etc. Prevalence of hookworm infestation is much higher than the general population because of their compulsion to work barefooted in the fields. Farmer's lung, hay fever, allergies of various types and fungal infections of the skin are some of the other examples of morbidities which the agricultural labourers likely are to suffer from.

In the profit generating exploitative socio economic pattern of production human labour has been reduced to a mere commodity. Least concern is made for this perishable tool (the labour) in the race of maximum profits. The working conditions adversely affect the workers health and in some cases prove to be fatal.

Pale skinned, thin dyspnoic labourers working in chemicals and pesticides factories : Pneumoconiosis affected child labour in slate, lead, silicon industry convey the same story.

We have made an attempt to focus attention on the health hazards which the agricultural labour is exposed to. We hope that it will initiate a debate which will improvise and enrich our understanding and contribute to the vital struggle for equality and justice.

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved.

Each issue of the journal will focus on one theme, but it will also carry (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

Our forthcoming issues will focus on : Politics of Population Control, Health and Imperialism, People in Health care and Systems of Medicine.

If you wish to write on any of these issues do let us know immediately. We have to work three months ahead of the date of publication, which means that the issue on Politics of Population Control is already being worked on. A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing style of reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. These need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be nealty typed in double spacing, on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions **in a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are working on issues of interest to you.

WORKING EDITORS

Please send me Socialist Health Review for one year (four issues). I am sending Rs. _____ as subscription and/or donation by Demand Draft/Cheque. (D.D. and cheque in favour of Amar Jesani or Padma Prakash, and for cheque, add Rs. 5, if outside Bombay).

Push Back the Catasrophes

I don't want a drought to feed on itself
through the tattoed holes in my belly
I don't want a spectacular desert of
charred stems and rabbit hairs
in my throat of accumulated matter
I don't want to burn and cut through the forest
like a greedy mercenary drilling into
the sugar cane of the bones

Push back the advancing sands
the polluted sewage
the dust demons the dying timber
thé upper atmosphere of nitrogen
push back the catastrophes

Enough of the missiles
the submarines
the aircraft carriers
the biological weapons

No more sickness sadness poverty
exploitation destabilization
illiteracy and bombing

Let's move towards peace
towards equality and justice
that's what I want

To breathe clean air
to drink pure water to plant new crops
to soak up the rain to wash off the stink
to hold this body and soul together in peace
that's it

Push back the catastrophes

POPULATION CONTROL : FOR OR AGAINST PEOPLE ?

Whereas Malthus related population and population growth to consumption, Engels and Marx related them to production. By the Malthusian hypothesis, population could be checked by means of forcing down the wages which would in turn lead to a natural increase in death rates. Marx posed the question as to whether overpopulation was in relation to the natural resources or to the needs of the prevailing system. This debate, the first on the issue of overpopulation represents to date the crux of the ideology supporting the reasons for population growth and consequently the measures necessary to curb it.

The capitalist mode of production as a prerequisite demands a surplus population from which an everready supply of human material — surplus labour — is created for exploitation. Overpopulation has therefore to be seen in terms of this mode of production and not as a consequence of the 'Eternal Laws of Nature' (Meek, 1971). In capitalist society the actual producers are alienated from the means of production because the latter are owned by the capitalist. Production is geared to the market demand and not to the human needs of the population. Therefore, the Malthusian prediction that growing populations would be the main cause of world-wide starvation is a historical error. The truth is not 'how many people' but 'how many people who can afford to buy enough food just to stay alive.'

In his polemical writings against the Utopian thinkers of his time, Malthus expressed contempt for the poor. He claimed that the unemployed poor were a burden on Nature's reserves and therefore, had no right to live, leave alone to reproduce. Biased heavily in favour of the English aristocracy, his pseudo-analysis about the 'inferior ranks of people' offers a rescue even today to population control propagators when they have to explain 'undesirable' events, the rational and truthful explanation of which can result in 'undesirable' consequences such as the conscientisation of the oppressed masses (Bondestam, 1980).

The Real Facts About Poverty

Malthus' observation that a reduction in population size would release the otherwise limiting resources is only apparently true. When the entire family lives at a subhuman level of subsistence, having lesser children does not increase the standard of living perceptibly. They still live below the poverty line; often all of their life is spent only in combating death from hunger and starvation. Escape from death however does not mean any improvement in the standand of living. Malnourishment, unhygienic conditions and strenuous physical labour, all together increase body weakness and decrease body resistance to acute and chronic disease. Morbidity creates further poverty (due to inability to work, expenditure on disease) and eventually leads to death. Either way death seems inevitable. The reason for producing or wanting to produce more children is economic and its resultant is the surplus lives produced.

Among the poor, the cost benefit of having more children is greater than when they have less. At a very young age, the child becomes either a direct wage earner or helps enhance the family income indirectly (baby sitting, filling water) by relieving the adults of household chores. Having many children is thus not only beneficial but also necessary because not all children that are born would live beyond the age of five. It is only when a steady income flows in regularly that having more children becomes a liability. A small family norm is a middle class value and to force the poor into accepting this norm without improving their economic and social conditions is inhuman.

Release of resources through population control is possible only when resources are universally available and uniformly distributed. The inequalities in access even to basic services such as health care become apparent through the fact that though 80 per cent of the Indian population is rural, only 46.2 per cent of the total health budget is allocated for this population. Worse still, the public health personnel are so overburdened with family planning responsibility that primary health care has become synonymous with birth control for the rural population.

The poor live in deficits and debts, therefore a reduction in family size will not create any savings. Population control cannot ensure that the released

resources, however insignificant will be invested to benefit the poorer sections of society. A fair distribution of resources is possible only in a socialist society where the means of production are distributed fairly. The propaganda that population control will release available resources is just an eyewash (Quadeer 1976).

Neo-Malthusians and The Ideology of Population Control

The Malthusian theory of arithmetic increase in food production and the geometrical increase in population and the ensuing doom was belied by bourgeois development in Europe in the 19th century as also through the import of this development into colonial India. It was at this point that the capitalist forces in the form of neo-Malthusian arguments introduced the 'population bomb' hysteria. Neo-Malthusian ideology was part of the reactionary counterstrategy against rising socialist forces. They propagate the view that demographic factors are the main cause of economic and social difficulties experienced by developing countries and to control natality is the neo-Malthusian solution. This propaganda is furthered to divert public attention from the real facts about poverty and in order to disorganise and weaken struggles aimed at democratisation.

The propagators of family planning can be broadly classified into people who apolitically and genuinely believe that population control is the answer to the world's problems and neo-Malthusians who use family planning to propagate their own ideology. But the distinction is not sharp. For instance Margaret Sanger who did pioneering work in challenging religious orthodoxy regarding contraception considered that the American public was being too heavily taxed to maintain a 'growing stock of morons' (referring to the American poor) who 'threatened the very foundation of American civilisation'. Her statement was recollected with fervour by the neo-Malthusians whilst unleashing a population control programme among poor Puerto Ricans with lowered intelligence.

The neo-Malthusian ideology holds the distribution of existing resources as being inversely proportional to the growth of the 'teeming millions'. The truth is that the existing resources are concentrated in the hands of a few in a capitalist order. The underlying fear behind this gross misrepresentation of facts is the imminent possibility of socialism gaining terrain due to the rising unrest among the unemployed and the exploited working class. Capitalists even today form the major donors to the population control funds throughout the world, either through private agencies or through 'legitimate' government bodies.

The Population Control Policy

The 1974 World Population Conference at Bucharest gave a call (in fact Dr. Karan Singh, the then Health Minister of India, did) for 'development being the best contraceptive'. Ironically, one year later, India plunged into coercive and inhuman sterilisations under the Emergency regime of Mrs. Gandhi. Even on the global level, governments of developing countries and private population control agencies were planning family planning as the primary strategy for development policies. Programmes were made more accessible, more attractive and more efficient (Wolfson, 1978).

Though donor agencies recognise social problems, very few have been prepared to support these activities without population control being the frontal strategy of approach to solve problems of poverty and unemployment. Maternal and child health (MCH) is the classical example where donor agencies have diverted their funds to, since MCH is closely related to fertility. Family planning comes along as an indispensable part of the package. Donors make it quite plain that they consider development to be impossible without curbing the birth rate. Family planning is the unavoidable condition to be fulfilled when a developing country asks for international aid.

In post-independent India, most of the leadership belonged to the upper and privileged classes. They often had westernised values and were sharply different from the people they were supposed to represent. Independent India had proclaimed socialism from the roof-tops but in truth only the Indian bourgeoisie as a class had benefited with the elite becoming more privileged day by day. Due to technical incompetence and the quest for profits, there was an increasing dependence on western countries for technical and monetary assistance. A vicious circle emerged because this dependence created further incompetence and servility. Foreign experts virtually shaped India's policies and also acquired a great deal of influence on their implementation (Banerji, 1980). As the economic condition of India deteriorated under free enterprise and lopsided development, foreign aid acquired a crucial role in shaping Indian policies. In the field of population control, western capitalists were able to push in their anti-third world ideology along with aid for 'development.'

India was the first developing country to begin implementing a national programme on family planning as a state policy in 1951. In 1963, a revised and extended variant of the official family planning (FP) programme was put into action. Population control (PC) has become a priority increasingly, in fact with fanatic fervour it has been proclaimed that PC is so urgent that it cannot await improvements in the economic and social fields. It is like putting the cart before the horse. Though the Fifth Five Year Plan promised a "frontal attack on the citadels of poverty" what was actually implemented was an inhuman, anti-poor PC programme.

The role of the Indian government in unleashing all the repressive state machinery on the poor for forced sterilisation has been condemned the world over (Wolfson, 1978). Yet, even today the use of force, pressure, utilisation of the bureaucracy and panchayats at village and taluka levels as well as monetary incentives have become accepted as a form of motivating people to accept FP. If PC is seen independent of development, then motivation and incentives are seen independent of the individual's social existence. Target methods and coercion can also be understood when PC is treated as a substitute for development (Mamdani, 1972). Family planning is much easier to implement than major advances in the areas of education or the economy and though it has been repeatedly stated that FP is part of the package of development, it has been thrust as a substitute for development and structural change.

The Feminist Perspective

It cannot be denied that birth control has created more options for women. Knowledge and availability of birth control measures is a matter of women's rights because women should be allowed to govern their own fertility. Repeated pregnancies and the drudgery of constant child-rearing not being conducive to good health, it is of extreme importance that women have access to safe and effective methods of contraception.

The disturbing factor however is that the aggressive incentive based population control programme has not allowed this right to stay with the woman. Policy makers decide whether a woman should have children, if so how many or whether she should be allowed to abort her own foetus. Doctors and social workers in clinics for abortion and contraception tend to adopt moralistic attitudes. Pharmaceuticals decide that women should passively accept the contraceptives that fetch the largest profits to the manufacturers. Third world women are constantly used for the field testing of dangerous contraceptives. Primarily black and Spanish-speaking women are targets of sterilisation in the USA. Cultural biases in India naturally compel a woman more than her husband to accept the FP operation and poor as well as lower caste rural women have been targets of the mass sterilisation camps as well as those for Copper-T insertions. Powerful patriarchial institutions in fact have strengthened their hold over the woman's reproductive organs through birth control.

Even the bourgeois state fills in the gaps either at home or outside it through population control and birth control. A woman's leaving home for a job does seem as though she has a greater freedom of choice, but in truth it is the flexibility and compulsion of the changes in the labour market that have left her with no choice but to enter the production force as a wage earner. Even if a woman is a wage earner, her family labour always comes first. The birth control policy monitors her 'reproductive' and 'productive' duties. Abortion laws should also be seen in the same context. Population control has increased state and international control on a woman's intimate physiological function under the guise of 'making available a birth right'.

The alarming anti-woman trend in the new reproductive technology (NRT) needs to be studied carefully. Unichem and German Remedies will probably be given the licences to manufacture the injectable contraceptive NET-EN in India. Hormonal implants which render infertility for upto five years are being tested on Indian women inspite of dangerous side-effects. Amniocentesis for female foeticide has been covertly recommended by FP propagators since girl babies are the future 'breeders'. Research to develop a 'male child pill' is being recommended (Postgate, 1973). With the growing concept of surrogate motherhood, women could be converted into breeders in a reproductive brothel where the most powerful socio-political control over women's reproduction would be made possible (Dworkin, 1983). Here, the 'valuable' ova and sperms from white couples could be merely incubated in the wombs of brown or black poor women, sterilised for convenience (Corea, 1984).

We open this issue with Ramala Buxamusa's article based on her Ph.D. thesis which exposes the impact that foreign aid has had on the Indian population policy. International aid to the third world for development contains major funds for

population control in an attempt to prevent the developing countries from becoming socialist. She traces how the initial resistance of the Indian government broke under international pressures.

Sucha Singh Gill's article convincingly examines the ideological content and class bias of the birth control programme. According to him, the emphasis of the Indian planners on population control is an attempt to weaken the class struggle in India.

In the third article, Kusha relates her experiences in a contraceptive testing unit in a working class area of Bombay. During her association with this unit for many years she saw contraceptives ranging from diaphragms to hormonal implants being tested for field trial on working class women inspite of the unpleasant and dangerous side effects they created. Her first hand experiences are eloquent.

Ilina Sen focuses on the motivational aspect in the family planning programme. When the earlier subtle motivations failed to increase family planning acceptance, the government plunged into an aggressive disincentive based coercive birth control campaign. Ilina examines the social and psychological theories on which the motivational strategy was founded and highlights the fallacies that accompany the present family planning programme.

Vimal Balasubrahmanyan takes a critical look at the trend in the incentives and disincentives in family planning without making a single comment! In a carefully prepared collage and not without a glint of humour, she traces the dangerous trend over a period of two years (1982-84).

The last article in this issue by Martha Giminez is reproduced from the Review of Radical Political Economics. She discusses the micro economic and the sociological theories that analyse reproductive behaviour and presents a marxist critique of the same. She argues that reproduction should be conceptualised in the context of a given mode of production.

SUBSCRIPTION RENEWALS

Is this your last subscribed issue ? A prompt renewal from you will ensure that your copy of Vol II, no 1 on 'Imperialism and Health' is mailed directly from the Press. Our first few issues were sold out ! So book your copies of Vol II, by renewing your subscription now !

Our subscription rates for Vol II have been revised –upwards. We are also offering you more reading matter by increasing the number of pages. New contribution rates :

For individuals—Rs. 24/four issues.
For institutions—Rs. 35/four issues.
Single copies : Rs 6 each.

Please add Rs. 5 on outstation cheques. D.Ds/cheques to be made out to **Socialist Health Review. Please write your full name and correct address legibly.** *It would help us if you could quote your current subscription number.*

PHANTOM SUBSCRIBERS !

We have three subscriptions sent by M.O. in the last three months which have no addresses. The only information we have about our phantom subscribers is as follows : (i) From Anthya M, somewhere in Kerala (ii) From somewhere in Karnataka, and (iii) From somewhere in the Hindi-speaking region ! If any of you know of people who have not received our acknowledgements for their M.O. please ask them to write to us.

The Printed Word

newsclippings on health and medicine, july – september 1984

Health Policy and the Health System

Deccan Herald, 21 July: A 58-year old man was electrocuted at Ram Manohar Lohia Hospital, New Delhi when the metallic stand for hanging the glucose drip came into contact with the overhead light, which had been known to be giving 'shocks'.

Business Standard, 2 Aug.: USAID has offered to develop basic infrastructure (buildings for health institutions, residential complexes) and to improve the health delivery system, (including family planning and maternal and child health) in Bhiwani Mahendragarh and Sirsa district of Haryana. In phase I the USAID has released Rs. 7 crores.

The Daily, 15 Aug.: Yet another patient of the ESIS hospital at Kandivili in Bombay leapt to her death from the third floor. The patient had been considered 'rowdy' apparently because she was not able to bear the pain due to acute apendicitis, for which she had been admitted a month previously but had not been operated upon. The reasons for the delay in operating remain unclear.

The Hindu, 30 July: The Working Group of the Central Council of Health and Family Welfare has made the following recommendations: (1) The creation of mobile opthalmic units in all districts and stringent action against unauthorised persons conducting eye camps; (2) A whole-time trained TB officer with supporting staff at the directorate level for proper suppervision and monitoring of the national TB control programme (3) All hyperendemic districts to be covered with multi-drug regimen projects during the 7th plan period; and (8) All states to repeal the Leper's Act of 1888.

Financial Express, 18 Sept.: The government has sanctioned a budgetary allocation of Rs. 547.46 crores for the central sector health programmes for 1984-85 as against Rs. 482.02 crores in the previous year.

The Telegraph, 19 Sept.: In the WHO regional committee for southeast Asia, India has offered its 'vast reservoir of trained medical manpower' to neighbouring countries for meeting their immediate requirements and in organising training programmes for their medical personnel.

The Hindu, 25 Sept.: The Eighth Finance Commission has recommended a monthly allowance of Rs. 400 for doctors serving in rural areas.

Hindustan Times, 28 Sept.: A steering group appointed by the planning commission has proposed the allocation of Rs. 13936 crores for health and family welfare in the 7th Plan. It represents 8.3 per cent of the total public sector outlay of Rs. 180,000 crores envisaged for the period. The health sector's share in the 6th plan was just 3.3 percent. Out of this, Rs. 10457 crores (about three fourths) will go to the family welfare sector.

Medical technology and developments in medicel practice

The Hindu, 12 Aug: By the end of 1984-85 three medical colleges in Tamil Nadu, all district headquarter hospitals and 22 hospitals at the taluk level in the state would be equipped to deal with accident and emergency cases.

Financial Express, 20 Aug: A production of Rs. 350 crores is envisaged in the 7th plan for the manufacture of medical electronic equipment. The Department of Science and Technology has estimated that a tentative investment of Rs. 60 crores would have to be made during the plan. During 1982, the total production was of order of Rs. 13 crores but is expected to rise to Rs. 20 crores in 1984. But the demand is estimated to be Rs. 45 crores worth. In 1976-77 20 MEE products termed 'life saving equipment' had been exempt from customs import duty. The list has now risen to 47 items.

Protests, Strikes and Agitations

Times of India, 8 July: 7,000 medical personnel of the Government and municipal hospitals —4,000 resident doctors, 1,500 post graduates, and 1,500 interns will go on an indefinite strike to protest against the Maharashtra government's decision to start private medical colleges accepting capitation fee. *(Contd. on page 147)*

THE DISASTER

A reaction to the tragedy at Bhopal

The saddest fact about the Bhopal tragedy—quite apart from the horror of the numbers involved — is that it was man-made. And the people who were responsible were **Not** the ones who suffered. As one newspaper put it, "Man-made disasters, like natural ones seem to show a particular affinity for the poor." Why did it happen ? Who were the victims ? These questions have a bearing upon distinct social and political realities in India in particular and the world in general, that have been forged for us by our ruling classes.

Consider our perspective for industrialisation for instance. We have borrowed not only the capitalist framework of development but begged and borrowed the capital technology of the industrial nations. Third world countries which have historically been the plundergrounds of today's advanced nations, have been put into a peculiar dilemma — the workers and the poor still have to fight for a decent living and a decent wage in a labour surplus economy, sometimes to the exclusion of struggling and fighting against other destructive forms which industrial capitalism has unleashed. Moreover, workers are first taught to despise safety equipment and regulations, as mere obstructions in 'productive' efficiency and then when they suffer, they are told it is because of **their** carelessness. And to compound it, workers are forced to live with occupational hazards—they are undertrained, safety systems and procedures are substandard. Issues relating to health and safety are overwhelmed by wage negotiations or depoliticised.

In other words, it is built into capitalism that health of workers or of others may be affected is a low priority investment area that eats into profits 'unnecessarily' (See SHR 1:3). In advanced industrial countries, there are groups — workers and environmental lobbies — which fight this tendency tooth and nail. But here in India it takes a Bhopal to jerk us into a state of elementary environmental consciousness and that too at such a huge loss of life.

And yet the events that led up to the disaster form a familiar story in many third world countries. A multinational company with a lot of political clout works hand in glove with a corrupt, heavily bribed government to safeguard its profits despite the laws and regulations of the land. Hostile administrators are transferred, and factory inspectors bribed. And then there are other advantages such as what Union Carbide gained—cheap underpaid labour from slums and bastis around. Whatever happened to the industrial siting and zoning laws ?

There has been much written about the tragedy, and some issues have become controversial. But some facts are indisputable. Without a doubt there was insufficient safety design built into the plant. Proper foolproof safety means precisely the ability to take care of such emergencies. But in Bhopal the scrubber was meant for smaller amounts of gas, and the water sprinkler system was inadequate. Why were there no computerised warning systems here? In American and European facilities, even storage areas have elaborate arrangements of automated sprinklers, foam generators and so on. We are scapegoats and victims precisely because our ruling class wants us to be. And then there were operational lapses. If slip blinds were not inserted at the right points or if some crucial valves were left open, it is dominantly the ideology of carelessness as subtly cultivated by the management because it helps in two ways—one, disregard for 'cumbersome' safety apparatus or rules enhances the pace of 'productive' work and two, in an accident a concerete 'careless' act can be identified and the blame put on the worker responsible for it. And what of the process and plant design ? A textbook (David and Stanley, see box) says that out of the three methods for producing isocyanates, only the one using phosgene is 'economically viable'. Obviously, if regard for the environment and people's health were to be a major criteria, there would be far fewer hazardous processes. Union Carbide had changed over to the MIC route for manufacturing the pesticide from the less profitable 'chloroformate' route even though the latter did not have MIC as a storable intermediate and was therefore that much less hazardous. It is ultimately a question of choice and very often, of the many alternative routes available, the cheapest and hence the most profitable is termed 'economically viable'.

The Information Monopoly

There is not much information available in 'open' literature on MIC and its effects on biological systems. The one source which could have provided this information was Union Carbide which either maintained a stoic silence or issued deliberate misstatements

to the public. Unfortunately the confusion was further intensified by our 'experts' who issued absurd and incorrect statements. And those who could have provided relevant information were instructed to be silent. In fact, by dramatising operations like the 'neutralisation' of MIC, scientists further complicated the situation. Rather than providing information and assurances backed by facts, our scientist-politician combine preferred to dramatise the situation and mystify technology. A demand for information and public access to records and to data is an important component of the demands put forward by a number of people's groups working on environmental and health issues. We have to work to pursue and support these demands,

(Contd. from page 145)

The Telegraph, 18 Aug. : About 6,000 junior doctors in all the 7 medical colleges in U. P. are on indefinite strike in protest against the alleged police assault on doctors of the Swaroop Rani Hospital in Allahabad.

Professional bodies in health care

Times of India, 25 July : Should doctors working full-time as medical advisors to pharmaceutical companies be allowed to hold office in professional associations of physicians ? The issue is being hotly debated following attempts by two doctors from multinational companies to seek election as presidents of two such bodies. The issue is of particular relevance in view of the coming election of the Association of Physicians of India, the largest organisation of medical specialists with a membership of 4,000. The post of president is being contested by two professors of medicine from Bangalore and Bhopal respectively and by Dr. Paul Anand, a full-time director of medical research of Glaxo Laboratories. Six months ago Dr. A. S. Kochar from the same company had sought elections as president of the American College of Chest Physicians (ACCP), but the attempt had failed on procedural grounds.

Indian Express, 21 Aug : A complaint has been registered against an alleged quack who was operating as a qualified medical practitioner. His credentials were first suspected by the manager of a bank which had granted the 'doctor' a loan. The Maharashtra Medical Council sources say that for each such case detected many others may go unnoticed.

Free Press Bulletin, 7 Sept : A doctor who is a Congress (I) MLA and the chairperson of the Maharashtra Small Scale Industries development Corporation has had his name struck from the registers of the Maharashtra Medical Council for negligence and violation of medical ethics a year ago, continues to practice. The complaint had been registered by a patient whose left leg had been crippled following a wrongly administered injection in the knee cap.

THE PRICE OF ASSISTANCE

The Family Planning Programme in India

ramala buxamusa

The evolution of the family planning programme has been greatly influenced by the foreign aid it has received. The author describes how (i) the nature and origin of 'aid' has changed and (ii) how and why the initial resistance of the Indian government to such aid crumbled. Not only the family planning policy but the methods of contraception promoted through the programme were determined by the aid, received directly from donor agencies or via international bodies such as the several UN agencies.

A commonplace assumption that goes virtually unquestioned these days is that the chief cause of every problem from the growth of slums to unemployment, famine, pollution, liberation, wars and strikes is overpopulation. Futurologists paint a pessimistic picture of the world in 2001 AD especially with regard to the third world and call for population control, that is family planning as the supreme panacea for all social evils. Similar views prevail amongst the Indian planners who accept the views that originated chiefly in the first world.

It is the hypothesis of this study that the present population policy is largely the outcome of factors other than mere socioeconomic and political changes in the country. The impact of external assistance as aid and loan received in cash as well as in kind has, over a long period of time, influenced the government's population policy. Although the government has shown ambivalence in implementing the population control programme, and although it is not officially accepted that the government's programmes rely largely on foreign aid, it can be proved that this external assistance has mainly been responsible for the population policy and programmes in this country. (1)

The Pre-Plan Period : 1947 to 1952

During World War II there was a lull in organised birth control activities. After the war statistical studies quickly gained momentum as valid science and "Asia's teeming millions" became a vital subject for investigation, particularly with the growth of political movements in India, China and south east Asia. The deepening food crisis in these areas frightened many American thinkers into the belief that they would turn communist (Borie, 1948).

As early as in 1946 the Swedish National Association, financed by some Americans tried to build up a liason between societies interested in population control but as the time was not ripe efforts failed (FPAB 1948). Later in 1948, with the deepening food crisis all over the world the Family Planning Association of Great Britain and the Swedish National Association under the leadership of Margaret Sanger organised the 1st International Conference on Population of the World : Resources in Relation to Family in London. Here for the first time the 'dignified' term of family planning, actually a euphemism was used in place of 'birth-control'. The conference stressed the importance of human fertility research and an effort was made to involve the UN body but met with no response from the UN (FPAB 1948). In 1948 was born the Family Planning Association of India (FPAI) as a private body. This body was affiliated to the parent body, FPA Britain from which it received funds in cash and kind. During this period there was no direct government aid nor multilateral (eg. UN) aid to India.

In 1949 China turned communist and this shocked the imperialist world particularly the USA. It's reaction and attitude was to "save India atleast". Many thinkers expressed the view that it was essential to check India's population (Vogt,1949). Thus fertility control in India and the third world became a priority for the US monopoly organisations. One hears of birth-control only from the mouths of Americans, Swedish and British individuals and their organisations in the pre-independence period. Catholic opposition did not permit the first world governments nor the UN to get involved in birth control programmes. Private organisations previewing "danger" donated funds to Indian private organisations to open clinics and publish literature to favour birth control. A beginning was thus made by the private organisations in the family planning field in India.

The First Five Year Plan 1951-1956

The nations which the imperialists feared would be lost to communism became known as the

population powderkegs" of the "underdeveloped" world and population control programmes were designed for them. India was selected for special attention. The first in-roads into the population control programme in India were made by private organisations such as the Hugh Moore Fund, the Rockefeller Foundation, the Ford Foundation and Swedish and British businessmen (Mass,1978).

Politically the subject of birth-control was sensitive. In the West there was Catholic opposition to birth-control, forcing private organisations to move with caution. The first approach was to spread the ideology of "overpopulation" through seminars, conferences, publications and through statistics. In 1952 the UN, for the first time, was pursuaded to collect the demographic statistics of the third world countries (Mass, 1978).

Rockefeller, Moore and other private monopolies which had been supporting population studies earlier now made moves to start private international organisations. In 1952 under the sponsorship of the National Academy of Science, John D Rockefeller III convened a conference of demographic experts and population specialists in Williamsburg, Virginia to establish a non-profit organisation, the Population Council. This organisation was to provide a previously lacking "respectable base from which to influence professional and academic sectors to finance a more scientific approach to population". Between 1952-58 the budget of the council was quadrupled, rising from 4.5 million dollars to 18.3 million dollars. A large part of the 1958 budget, 8.4 million dollars was provided by Ford Foundation. It is said that over 500,000 dollars, nearly 80 percent of all the Ford's Fund for population control came to the Population Council. The Rockefeller Foundation also donated 3.4 million and the Mellon family 2.9 million dollars to Population Council (Mass, 1978).

With the creation of the Population Council in New York, British and Swedish businessmen were moved to organise the Third International Seminar in 1952 at Bombay. The Family Planning Association of India (FPAI) managed the show. Many foreign European dignitaries who attended expressed Malthusian views and an International Planned Parenthood Federation (IPPF) was founded, with headquarters in London. Swedish and British monopolies were not able to donate as much as American monopolies and in the 1950's IPPF's budget was comparatively less than that of Population Council. It supported all the affiliated Family Planning Associations of the world. India being the major target of attention, Lady Rama Rau was made the first joint secretary along with Margaret Sanger the pioneer of the birth control movement (FPAI, 1980-81). Margaret Sanger's views on birth control sound markedly racist today; she held that the growth in numbers of poor of the world was a burden and a threat to the peace of the "civilised" and needed to be checked.

India accepted the need for population control and incorporated a family planning programme in its health ministry. It officially opted for the clinical method and the opening of clinics. But in the first three years only the rhythm method was propagated. Private organisations such as IPPF and the International Red Cross donated in cash and kind to their clinics using diaphrams, foam tablets, condoms and conducted sterilisation operations in Bombay and Calcutta. These FPAI clinics were the first of their kind in the world (FPAI annual reports). Sanction for the use of contraceptives (mainly condoms, foam tablets and diaphrams) in the government's own clinics and the Rockefeller and the UN sponsored projects in Punjab and Bengal respectively was given only in 1955 (Ministry of Health Reports, 1952-1956). The Government's action in the first plan was negligible. This is confirmed by the fact that although the government sanctioned as much as Rs. 65 lakhs, no more than Rs. 31 lakhs was spent. This could not be due to mere moralist objections to artificial birth control programme alone. The need for birth control although accepted in principle by our planners, was not felt to be such a great necessity. Hence the difference between allocation and implementation persisted over many decades.

The Second Five Year Plan : 1956-1961 (March)

During this period, the liberation movements in the third world grew stronger. The economic condition of most of the third world deteriorated. For instance, India faced its direct majer foreign exchange crisis in 1957 when the rupee was devalued. At this time, Coale and Hoover rejected the classical Malthusian theory but postulated that due to economic improvement death rates fall but not birth rate, and therefore, economic development is not possible. Thus the argument popular in the west was that investments in population control were more beneficial than investments in development programmes (Coale and Hoover, 1958).

Third world governments however, were not keen on finances from private donors. The Ford

Foundation and the Rockefeller Foundation finding that they instead were being cold shouldered helped in funding the UN. The UN also received funds from the Population Council. In 1956 the UN carried forth the recommendation of the International Social Science Council to collect demographic statistics (ECAFE, 70). It later moved two governments in the third world—one in Asia in 1957 and other in Latin America, to start demographic training centres catering to the people of neighbouring countries. In these institutes consultancy services wers supplied by the UN. Most of the consultants were generally officials on leave from private population control bodies (for instance, Parker Mauldin, an Officer of the Population Council took leave from his office and came to the Bombay Demographic Training Centre as a UN Consultant on the subject) (Population Council Report, 1957). The idea was to train third world people in demography in order to spread the awareness of the need for population control. Thus ironically a member of the Population Council, (the ideology of which was not accepted by the third world), was allowed to help in training and advising Indians on the subject, as he came in the guise of a UN expert. **This trend of private organisations infiltrating the third world through international bodies like the UN and thus gaining acceptance is continuing even today.** It is in this way that their unacceptable ideas influence the population policy of the third world.

The WHO was in fact, severely critcised for organising such programmes for curbing population and controlling tropical diseases. This was interpreted as being not so much for the benefit of the third world, as for providing lucrative business for European and American drug cartels (Mass, 1978.) **An analysis of WHO's own reports reveals that the projects funded in the third world mostly relate to field and human trials of the drugs and chemicals being developed by first world firms** (Times of India, 1981) **Critics point out that but for these programmes, the firms would never have been able to develop the products or conduct such trials in the third word on their own.**

At the same time the Population Council, independently started aiding demographic teaching in Asian and African universities and began collecting demographic statistics as well so as to spread awareness for the need to control population growth. However, in the name of action research, they also carried out the testing of certain contraceptives which had not been tested or approved by their own government. The first world Drug Laws were too stringent and the lax laws of the third world on the other hand, offered wide opportunities for such testing.

The Ford Foundation, which had earlier showed interest in population control through other organisations now took a bold step. It independently started organising population control programmes in the third world, with its first programme being in India in 1959 (Ford Foundation, Report 60).

In 1956-57 the Indian government showed great resistance to private organisations aiding the family planning programme, although they accepted in principle the need for population control. But in 1958 faced with financial crisis the government's resistance broke down a little. India called for development aid from foreign countries which brought in aid first from the Ford Foundation that year and Bonnie Mass has stated that in 1959 India received 9 million dollars for publicity and campaigns for population control (Mass, 1978). Later others came with aid for agriculture and small industrial development. Along with development aid came assistance for population control. Various Universities departments of Economics were aided by the Population Council to start teaching demography.

One notices a strange situation here: the Indian government allowed the private organisations to directly carry out certain population programmes but did not itself get totally involved in the programme. However it began to show a keen interest in implementing population programmes. Several demographic training and research units were started by the government and plans were made to carry out empirical research on contraceptives previously tested by FPAI in their clinics. Oral pills and different methods of sterilisations were tested by the end of the plan.

The government expenditure in the second plan was ten times more than that in the first plan. This may have been a result of increases in foreign aid for FP after 1958. One also notices that after 1958 the private voluntary agencies were getting more funds from private organisations and increased their activities. For instance, FPAI started more programmes as its funding organisation the IPPF got 66600 dollars from the Population Council in 1959-60 (UN, 1968).

Third Five Year Plan : 1961-66

With the continuation of the cold war, came a tremendous investment in defence all over the world. Economic stagnation and inflation pressures hit the

first world. As a chain reaction third world countries were the most affected. The UN economic survey report of 1963 indicates the widening gap between the first and the third worlds. All this affected private organisations and they became more interested in selling the idea of population control. They attempted to involve the American government, but president Eisenhower rejected family planning (Wiessman, 1970). Many writers persisted in their argument that Vietnam and other liberation wars of Asia, Africa and Latin America were the result of overpopulation. Therefore population control activities were most essential in the third world. Still others stressed that the widening gap between the first and third worlds was due to third world overpopulation. (Berelson, 1964).

The growth of pessimistic thoughts about the overpopulation of the world caused some of the private organisations of USA for instance Draper, Moore, Harper & Row, Cass Canfield and Rockefeller to set up the Population Crisis Committee which was the political action arm of the Population Control movement. The US government officials served as representatives in the above committee (Wiessman, 1970). With the consent of President Kennedy, Richard Gardener was allowed to offer aid for the Population Control Programme of the UN marking the beginning of US government aid to population control (Chandrasekhar, 1969).

With a programme from J D. Rockefeller III, the White House gave a 'New Look', to foreign policy. USAID made birth control a part of foreign assistance and permitted President Johnson to judge a nation's "self help' in population planning as a criterion for giving Food for Freedom Aid. Developed rich nations thus directly pressurised underdeveloped poor nations through economic aids which the poorer nations could not refuse (Wiessman, 1970).

In India, by the end of the second five year plan it was realised that the economic plan targets were difficult to reach, secondly the policy resulted in widening the disparity in people's living standards. (Report 1960-61). In 1962 the Ford Foundation advised the government to take up the extensional approach ie to carry FP service to the door of the client through mobile units camps and clinics. Besides Ford the other major donor to the Indian Voluntary agency FPAI was IPPF whose joint secretary was Dhanvanti Rama Rau. The Ford Foundation and FPAI experimented with mobile units and sterilisation camps and IUCD, initiating the period of bio-medical testing in India. (Ford Foundation, 1961-66).

India was the first country in the world to experiment with sterilisation and its result was utilised to formulate a sterilisation programme for the world (Population Report 1973). The government at the beginning of the plan paid no heed to the recommendations of the Ford Foundation but later in 1963 with the increased economic crisis, accepted 'the extensional approach' (UN India, 1966). Was the government's willingness to permit experiments by foreign institutions before its acceptance of the programme due to a fear of mass reaction, or was it due to foreign pressure ?

Thus we see that the private bodies gave up doing research in demography and moved directly to support action programmes. The money allocated in the third plan by the government was forty times greater than that in the first plan and foreign private agencies contributed more money to family planning. In this plan period, although the reports do not clearly indicate the relative proportions of foreign private aid and multilateral aid (Health Directorate Report, 1961-66).

The Three Annual Plans : 1966-69

The prolonged war in Vietnam continued to drain US wealth, while severe inflation hit many countries of the first world. The painfully slow rate of economic growth was noticed not only in India but in all the third world countries. Population control continued to siphon off funds from development. As a result of this, all the food shipments of USA "Food for Peace" programme under PL 480 aid to the third world had to be expended on Family Planning ie birth control programmes (Cleaver, 1973) USAID and many suspectedly private organisations moved to give population control a more international touch.

The Ford, Rockefeller, Moore and other foundations began to give larger donations to the international agencies resulting in larger budgets for the Population Council and IPPF. Among their many activities was especially encouraged the distribution and testing of contraceptives. In 1966 the Population Council went on to emphasise the use of Lippes' loops which had already been discarded in the west. They were either donated freely as aid to the third world countries or else loans were granted for their purchase or were manufactured in third world countries. In India, the Population Council funded the opening of the Lippes' loop factory at Kanpur, the

machinery for which was sold to the government by the Council (Population Council, 1966).

USAID donated assistance in cash and kind for population control along with development and food aid to India. In April 1966, the Population Council's bio-medical division continued to fund the testing of contraceptives and launched the International post-partum family planning programme. This was to start more direct FP assistance through a hospital base to all women who came for delivery or for Medical Termination of Pregnancy (MTP). (Mass, 1978). Although the acceptance of family planning appeared voluntary, the very fact that it was linked with delivery and abortion facilities detached it from the free will and volition of both the women as well as the hospitals that opted to receive the programme funds. But until 1969 funds for the post partum programme did not reach India (UN Report, 1970). Today this post partum programme has resulted in the acceptance of family planning measures being made a pre-requisite for obtaining medical treatment for deliveries or abortions. Thus a strange form of "compulsion" was created not overtly, but by skillfully narrowing down choices for women.

Faced with growing opposition from third world radicals and nationalists, private monopoly houses tried to move more cautiously. Through the UN a multilateral touch was given, by making family planning a human right in December 1966, adopted by 12 countries and later by all UN countries within a year. This resulted in the WHO, UNICEF, ILO, ECAFE and UNESCO directly donating funds for family planning and supplying contraceptives (UN Assistance 1968). In 1967 the United Nations Population Trust Fund (UNPTF) was formed whose major financial resources came from US donors and the USAID. In 1969 UNPTF became the UN Fund for Population Activity - UNFPA - and by the seventies, UNFPA dominated population control activities in the world (Mass,1978). With growing antagonism USAID routed its funds through small as well as better known organisations such as Pathfinders and the IPPF. Private voluntary agencies in the third world were also willing to use their good offices to put to test oral contraceptives and experiment with the effectiveness of various delivery systems of family planning in their respective countries (OFECD, 1975).

In India The Third Five Year Plan was greatly lagging behind in its targets in 1966. The country was faced with another great economic crisis resulting in a severe drain on it foreign exchange. During this period it is interesting to note that the "Development Aid" was bracketed with the family planning programme. The USA instead of signing annual or multiyear (food) sales agreements deliberately doled out food only for a few months at a time to ensure, through pressure, that family planning programmes were carried out. One notices that aid from USAID was the greatest to India during this period. It not only supplied money and PL 480 funds (such as oral pills in 1967-68 and then condoms for the Nirodh Marketing programme for testing as well) USAID in 1966-69 donated funds to start the "Intensive District Area Programme" providing nutrition programmes along with family planning. By 1968 SIDA, DANIDA and Japan signed the bilateral contracts with the Indian government and supplied contraceptives and equipment for family planning services (Ford Foundation, 69). Private organisations like the IPPF, Pathfinder and the Population Council which function through voluntary organisations tested IUCDs of different types and shapes oral pills were tested and sterilisation experiments were conducted in their voluntarily-run clinics, hospitals or dispensaries.

One notices that with each plan the priority accorded to the different methods of contraception has changed. In 1966-67 the government's stress was on IUCD; in 1967-68 sterilisation was officially emphasised and in 1968-69 it was Nirodh (Ministry of Health-Family Planning, 1966-69). Were these changes made by the government as a result of mass demand ? or were they the result of the supply of contraceptives as part of the external aid as India did not produce them indigeniously (UN,1970) ?

The government allocated in the first annual plan Rs. 149.30 million, in the Second annual plan Rs. 310 million and Rs. 370 million in the third plan for family planning. Incentive schemes were given emphasis in the second and third plans. One notices nearly a 100 percent rise from the sum allocated in the first annual plan. In this plan period almost 84 percent of the allocated funds were spent (Ministry of Health, 1966-69). This may have been a result of USAID compulsion to expand the FP activities and the PL 480 funds or it may be because the incentive schemes were offered to the acceptors and promotors of family planning. The most prominent trend in this period is the increase in direct involvement by the first world countries and the UN, instead of only private monopolies and their international organisations. With this the pressure for acceptance of family planning by the third world, especially by India, becomes greater and more rigid.

This desire for limiting population led to a marked increase in bio-medical testing to discover "the best contraceptive". In many cases women were not even aware that their bodies were being used for experimentation since they had approached the clinics for other medical treatment. Worse still others, because of financial incentives, sold their bodies to be used as "guinea-pigs" for experiments, the result of which could not be guaranteed; doctors themselves could not often predict possible reactions (Scheuer, 1972)

Family planning now became a goal to be reached, a tempting solution to the financial crisis and thus the human element was completely ignored. Protection of basic human rights, especially the rights of women, which the UN proposed as the aim of this programme, were completely ignored.

The Fourth Five Year Plan : 1969-74

The green revolution in certain parts of the world increased food production; but the Vietnam was continued to drain USA's public investments and world-wide inflationary conditions instead of improving had further hiked prices. Liberation wars and guerilla movements developed in the third world. All these conditions moved the private and government donors of the first world to loosen their purse strings for population control activities still further. During this period we see that the development aid increased in absolute terms but one can observe that the rate of growth for population control aid was much higher as compared to that in 1961. Development aid increased from 5200 million dollars to 7800 million dollars. Population assistance rose from 6 million dollars to 198 million dollars (UNFPA, 1974). In 1969 President Nixon in a revealing message to the committee of the White House stated that the UN, its specialised agencies and other international bodies should take the leadership in countering the problems of overpopulation in the third world and that the US should co-operate fully with such programmes (Singer 1971).

All this created a climate for symposia, conferences and debates on the population problem. The chief cause of every problem was seen as over population. Economists worked out the cost-benefit analysis of population control investment versus development investments insisting that the former was more beneficial than the latter. The World Ban received for the first time donations from the US and other first world countries for activities in population control. Under the leadership of Robert McNamara it frantically called for population control and assigned from its budget 27.0 million dollars in 1973 (World Bank) in India. The World Bank started population project in Rajasthan and Andhra Pradesh in 1974.

USAID, faced with objections from many third world countries rechanneled aid through multilateral and a few private international agencies. By 1973 100 million dollars of AID Funds entered the developing countries once again through private organisations for population control activities. By 1971 many new private organisations such as Family Planning International Assistance, Association for Voluntary Sterilisation, Asia Foundation and the International Confederation of Midwives had been founded. Pathfinder, a private organisation receiving funds from USAID had by 1973, 35 projects in 44 developing countries which were funded directly by private organisations and not by governments of the third world countries. IPPF in 1973 launched programmes to integrate family planning with rural development and when its activities expanded, it received increasing recognition by government. (USAID, 1973).

USAID was very keen on promoting bio-medical research and in developing new contraceptives. It donated 3 million dollars in 1970 to the Population Council to develop the "once a month-pill" and the Indian Council Medical Research Unit cooperated in testing in India (USAID, 1973).

In-mid-1971 when the New York Population Council started its International Committee for Contraceptive Research (ICCR), in India a Contraceptive Testing Unit (CTU) in Delhi with 14 centres in different cities of India was set up. This duplication was unnecessary as already there existed the Institute of Reproduction in Bombay which had its centres in major cities of India. The ICCR tested intra-uterine device on 50,000 women over a period of one year. The ICMR has conducted research on various intra-uterine devices and hormonial contraceptives. About 50,000 women are estimated to have taken part in these tests for the ICCR.

It is interesting to note that the population control activities which were started in 1952 by foreign powers with the sole emphasis on demographic research were transformed by the 70s into direct population control of the third world people. IPPF was the only international private organisation whose budget rose very fast as this organisation concentrated on family planning activities and worked on a voluntary basis in third world countries. But the budget of other private agencies like

Rockefeller, Ford Foundation did not increase and private organisations and USAID started donating more liberally to IPPF.

India, despite enjoying some fruits of the Green Revolution due to an increase in food production, could not check the growth of poverty and unemployment. The inflationary crisis continued to increase as well. World-wide inflation had further worsened her economic conditions. The Indo-Pak war for the liberation of Bangladesh further upset her economy and in 1971 the Indo-Russian pact strained her relations with USA triggering off other repurcussions.

The family planning programme was again given the highest priority and the population policy became in principle more ante-natal. Upto 1970-71 USAID and Ford Foundation had given major support for family planning. Their consultants advised the Planning Commission, the Health Ministry and the ICMR. When relations with the US were strained USAID and Ford Foundation were asked to wind up their population control units and their aid ceased to flow (Seal, 1974).

After a little lull in donations in 1971-72 funds from multilateral organisations and other governments were gradually stepped up. One sees SIDA, CIDA, UK and Norway donating large funds to support the building of the National Family Planning Institute in Delhi and some research on nutrition and health programmes in India. UNFPA, ILO, UNICEF and WHO, whose activities were limited in India gradually became the major donors. Both private and multilateral bodies were heavily supported by the USA. By the end of the plan an experimental area development scheme — India's first population project — was launched by the government with aid from the World Bank, IDA and SIDA. When USAID stopped functioning directly, many voluntary private organisations like IPPF, AUS, Pathfinder Fund, FP International Assistance, Christian Church Associations, and the International Red Cross started funding small voluntary organisations in India and thus many rural and urban clinics, hospitals and dispensaries were opened. The organisers were invited for seminars and conferences abroad and they were donated contraceptives and money. Many organisers came back and stressed sterilisation and offering incentives like radios, buckets, sarees, transistors.

In the Fourth Five year Plan Rs. 315 crores were allocated but government expenditure after 1972 reduced as USAID and Ford Foundation found themselves in disfavour at the government level as a result of the Indo-Russian pact. The USAID policy statement indicates 'AID recognised early that many instrumentalities would need in helping developing countries to attack their problems of population growth. Direct assistance could be helpful in those countries receptive to the bilateral approach. In some others however, assistance from multilateral agencies and from private organisations appeared to be more welcome — thus USAID shall help multilaterals and private organisations and they shall work independently".

The Fifth Five Year Plan : 1974-79

The decade of the Seventies began with a further upset of the already deteriorating world economy — the oil crisis hit the western world. At this crucial period in 1974, the World Population Year was celebrated and the activities of population control expanded. The first international conference on population sponsored by the UN was held at Bucharest. Various proposals and plans of action were put forward which would drastically reduce birth rates in the third world Planners of the conference were confident that they would be able to strike an agreement on 'plans of action' for family planning. Surprisingly third world countries formed a powerful block and opposed the US experts' 'plan of action' intended to stabilise the third world's population growth, treating birth-control as a factor which could be detached from the health and well-being of the women, family and society. Many of the socialist countries protested against what they considered the absurd theory of "population explosion." They felt instead that development would itself bring down the birth-rate. (Mass,1978) Experience had shown that poverty was the main factor responsible for over-population. Hence they argued that to insist that family planning was more important than development was to see the problem from the wrong end.

The social and political consciousness of the third world made it necessary that population programmes of the future would have to be couched in more subtle terminology. In order to make it palatable to the third-world recipients John D Rockefeller II was the first to put population planning in a developmentalist framework. He argued that population programmes and overall development programmes should indeed go hand in-hand. "We recognised that reducing population growth is not an alternative to development, but an essential part of it for most countries" (Mass, 1978).

Though there was a protest and an apparent setback for imperialists at Bucharest, the working group of the conference comprised representatives from many countries who chose to make the final draft. They voted to retain neo-Malthusian 'target' figures which proposed that the birth rate of the underdeveloped nations be reduced to an average of 30 per thousand by 1985. Despite the vehement protests of the third world, the end results of the report of the conference were heavily influenced by the opinion of the first world.

The Population Council concentrated on its bio-medical testing even after 1975. Till 1975 the International Committee for Contraceptive Research carried out tests on 12 new potential fertility control methods. However, faced with objection in the third world the Population Council handed over the post partum projects to UNFPA and donated large funds to it (Mass, 1978).

The Pathfinder Fund with a budget in 1965 of 100,000 dollars expanded in 1975 to 3.5 million dollars and supported approximately 150 studies in more than 40 countries. Its office in New Delhi which was set up in 1964 was later closed down (Mass, 1978).

By 1975 the Family Planning International Association funded by the Planned Parenthood Federation of the American IPPF and other voluntary world church organisations, services aided by USAID became the single largest source of contraceptives and other family planning supplies to the third world. Nearly 1000 church related hospitals, clinics, dispensaries and private groups were supported.

The Co-operative for American Relief Everywhere (CARE) began by 1970 to support birth control and by 1975 gave birth control the highest priority. Many other private organisations like OXFAM (England, Canada), Christian Aid (England), Asia Foundation, American Voluntary Association for sterilisation supported family planning ie birth control as their highest priority projects (UN, 1979).

UNFPA whose activities expanded in 1974 and which was in charge of the world conference split up its global role of population assistance into three phases by mid-1976 : (1) Traditional technical assistance-transfer of technical know-how (2) Financial support to assist government and non-government bodies to expand activities. (3) Phasing out of assistance or foreign experts at the country level which will expand the programme.

India's economy suffered grave setbacks due to world inflation. In response to the Bucharest conference, assistance from the UN, as well as voluntary organisations took a more subtle form and was linked with rural development, child care and nutrition. For example, families accepting birth control were given free tube wells, free meals, or free maternity and child health benefits. The government too accepted this approach and integrated family planning with nutrition. This can be seen as a method of making family planning a prerequisite for nutrition benefits from the government.

Meanwhile, after the 1971 war, political consciousness was reaching a new peak with mass peasant uprisings throughout India. The movement by Jay Prakash Narayan was to have important consequences for the future. The political overtones of this and other movements and the insensitivities of the ruling party led to the declaration of the emergency and the upsetting of the five year plan.

In 1976 the central goverment in an important move to make state governments accept the family planning decided to freeze the population based at the 1971 level for the next 25 years for determination of representatives in the Lok Sabha and state legislatures. This compelled the leadership of many of the states to accept compulsory sterilisation and offer incentives viz. Rs. 150/- if performed with two living children, Rs. 100/- if with three living children and Rs. 70/- if performed with four and more (Times of India, 1976). Maharashtra declared that government servants who were not sterilised and had more than two children would not be given ration, housing facilities, or free hospital services (Times of India, 1976). To add to these frightening and unjust disincentives, in the Pune Municipal Hospital a sick person was not admitted unless and until one family member was sterilised and produced a certificate. All these measures led to great opposition to family planning among the public and to the Congress regime and the Congress was voted out of power. With the advent of the Janata Party, Raj Narayan, the Health Minister modified the Population Policy. He eliminated all forms of compulsion and gave family planning a new dignified name — family welfare programme, which in substance remained the same.

In this plan as compared to the earlier one, Rs. 497 Crores were allocated. The major donors during the Fifth Plan were UNFPA — 40 million dollars; World Bank — 21.2 million dollars, and SIDA — 10.6 million dollars.

With more funds coming in, the expenditure rose in each successive year. For e.g. in 1976-77 it increased almost to Rs. 16793.89 lakhs mainly due to the so-called incentives for sterilisation and IUCD programmes. Although it increased during Janata regime there was a fall in the expenditure and surprisingly enough, the external aid received during those last two years of the plan exceeded earlier donation. This was because during the Janata regime, "family welfare" (nutrition, child welfare, post-partum programmes) were used as a bait. Before the sixth plan began in 1980 a year passed without a five year plan but activities on Family welfare increased during this year.

The Sixth Plan : 1980-85

With the world situation remaining practically the same, with increasing recession, the emphasis on the need for population-control continued. Bilateral aid, earlier rebuffed, was now welcomed by the Indian Government. Permission for adoption of villages in the third world by the UN and by the World Bank was now extended to bilateral organisations like USAID, CARE, SIDA and others. In India too this became a common feature. Monetary crisis has made India sign a development pact with many First World countries. Although the total figures of external aid was not available, the Indian government allocated Rs. 1010 crores for family welfare of which Intensive District Development (ie development of primary health centres and family planning in districts by multilaterals and bilateral units) accounted for nearly Rs. 225 crores (UN, 1980-81). The India Population- II programme of Intensive District Development based on the experience of Population-I programme was extended. Their aim was "to promote family welfare to lower the fertility rate through the creation of facilities for integrated delivery of services for health, nutrition, MCH, contraceptives and medical termination of pregnancy, closer to the homes of people particularly in rural areas" (USAID, 1980-81).

The external aid for India Population Project-II has involved many donors The multilaterals UNFPA and the World Bank consented to support projects in 18 districts with 95 million dollars. Performance Budget, 1980-81). On examining bilateral involvement one finds that USAID which had stopped donating for the family planning programme since the Indo-Soviet pact of 1971, agreed to donate 40 million dollars supporting 12 districts and the above project is still being implemented (USAID paper, annexure). Further UK and DANIDA who had earlier supported the sterilisation programme and National Health and Family Welfare Centre building funds, donated 63 million dollars to carry out family welfare and health programmes in 15 districts (Performance Budget, 1980-81).

It is not easy to get statistics on the foreign contribution to family welfare but one is aware that a good quantity of Copper T manufactured by the Population Council has reached India, and today besides sterilisation, this is the foremost method of family welfare adopted by the government for which substantial incentives are being given.

The state of Maharashtra which was declared as the foremost in the use of Copper T for three consecutive years was exposed in a racket uncovered by the Indian Express (1984). The number of eligible couples in Maharashtra, were found to be much less in number than the acceptors of Copper T ! When the government field surveys for inspection were conducted, it was found that nearly 25 percent of the copper Ts inserted ie 726 lakh Copper T inserted, worth four crores were fictitious cases.

The annual reports of ICMR indicated that the Population Council, Ford Foundation, and WHO continued to give funds for bio-medical contraceptives research. The FPAI received laproscopes from IPPF in 1979-80 and organised camps in rural areas. For example a welfare organisation in the village of Tara, used laproscopes in Raighad District while the taluka hospital had none. A demand for laproscopes was made. Thus by 1984 almost all districts of India, especially in Maharashtra, got laproscopes.

In 1970 the direct involvement of Ford Foundation which had started since 1959 was stopped. In 1971 JRD Tata founded the Family Planning Foundation of India (FPFI) and the Ford Foundation stepped in as one of its major donors. (Ford Foundation, 1980).

The FPFI by 1972 took up action-cum-research projects, demographic research and later biomedical testing of contraceptives. The activities which were initially directly handled by the Ford Foundation were now aided by it. Its role thus remains important even today, and its philosophy continues to influence the Indian population policy. In 1979 the Ford Foundation donated 700 000 dollars ie almost 50 percent of the FPFI's total budget (Ford Foundation, 1980). Though the acitivities of the Family Planning Foundation began during the Fifth Plan period, it was only during the sixth plan period that it took on a more prominent role to carry forward the philosophy of the Ford Foundation by organising and founding seminars, conferences, action research. etc.

Table 1

Nature of Assistance of Imperialist Powers to private voluntary organisations and the government for Family Planning Programmes and central government plan allocations :

The following data has been tabulated to (a) understand why the population policy has undergone changes and (b) to find out what the impact of the external assistance ie. private, government and multi. lateral (2) has been, and (c) how and in what way it has affected Indian programmes.

Phase	Plan Period	Donor Agency to India	Recipient Agency in India	Central govt. allocation for FP
I	Pre Plan 1947-1952	Private	Private	British government had no programme
II	First Five Year Plan 1952-1957 March	Private Multilateral	Private Government	Rs. 65.00 Lakhs
III	Second Five year plan 1957-61 March	Private Multilateral Private	Private Government Government	Rs. 479.00 Lakhs
IV	Third Five year plan 1961-66 March	Private Multilateral Private Government	Private Government Government Government	Rs. 269.70 Lakhs with provision for Rs. 500.00 lakhs
V	Three Annual Plan 1966 to 1969 March	Government Private Multilateral Private	Government Government Government Private	Rs. 750.01 Lakhs
VI	Fourth Five Year Plan 1969 to 1974 March	Governments Multilateral Private Private	Government Government Private Government	Rs. 3150.01 lakhs
VII	Fifth Five Year Plan 1974 to 1979 March	Private Multilateral Private	Private Government Government	Rs. 4970.00 lakhs
VIII	1979-1980	—	—	Rs. 1180.00 lakhs
IX	Sixth Five Year Plan 1980 to 85 March	Multilateral Private Private	Government Private Government	Rs. 10100.00 lakhs

Note :- Figures of Donation received not indicated as assistance is in cash and kind.

(Mimeograph)

Summary and Conclusion

In the pre-independence period the efforts of birth control were carried out by a few concerned individuals in India. A couple of foreign organisations funded Indian birth control clinics. There was no state level movement.

In the First Five Year Plan the Government accepted family planning as a programme. The major emphasis particularly in the early years lay on the rhythm method, due to the diffidence of the government. Private organisations funded generally by private organisations were free to propagate other methods.

In the 60s the increased economic crisis, the shortage of food, the growth of liberation movements brought first world governments to focus their attention on the importance of population control to avoid major social and political upheavals. Development aid was increasingly linked to population programmes and there were an increased aid flow from governments of the First World to the governments of the third world.

In India, the programmes of voluntary organisations served as important pointers as to what direction the government policy would take. It was also their advice and donation which compelled the government to change prescribed contraceptives during each plan period. It gave or promoted what it received and tested what it was asked to as the economic crisis made them helpless and forced them to accept assistance which led often to indebtedness.

After the World Population Year, 1974, the approach has again changed. It is now recognised that development is essential for birth control programmes to make a headway. Thus increasingly the trend is to support 'integrated' projects which include health, nutrition, and development. Multilateral and governmental aid have become the major source of finance for the Indian govenment though it still remains to be analysed whether these programmes are development oriented or whether they are basically family planning programmes with merely an acceptable cover.

The point of this article, is not merely to criticise the idea of birth-control itself which should be available to women as their basic right. This paper is also aimed at examining the history of the fallacy that family plannining is a solution to the problems of poverty, underdevelopment and unemployment. Has the bogey of overpopulation been created by the leaders of the first and third world countries and exaggerated merely to divert attention from the real problems facing them ? More important have the woman's basic needs been forgotten in the quest for ever-higher targets of achievement in family planning measures? Do we in the Third World want a reduction in the birth rate, at any cost ?

NOTES

1. *Performance Budget* 1977-78 Ministry of Healh and Welfare Government of India P. 184 "The expenditure on the family welfare programme is basically met out of the national exchequer. Some assistance which forms a small proportion of the total expenditure on the programme is received by way of international cooperation from some of the international agencies".

2. *Private Donors* to India are most often the monopoly houses or its funded voluntary organisation. Many of these voluntary organisations are also funded by government aid agencies eg. The Ford Foundation, the Rockefeller Foundation, Hugh Moore Foundation, International Planned Parenthood Federation, Population Council, Pathfinder Funds,Medical Christian Association, International Red Cross, Peace-Corps, OXFAM, Population Crisis, Voluntary Sterilization Association and other private receiving agencies, Family Planning Association of India, The Family Planning Foundation, Indian Red Cross, various Rural & Slum Developmental Agencies, Gandhigram Institute etc.

3. *Multilateral Donors* are the agencies funded by more than one monopolies and governments such as bodies of United Nation and recently the World Bank eg. WHO, ECAFE, UNICEF, UNFPA, IDA and others.

4. *Bilateral-Government* - First it was USAID United State Aid to Developing Countries, NORAD Norwegian Agency for International Development, BODA British Overseas Development Assistance, SIDA Swedish International Development Authority, DANIDA Danish International Development Agency, CIDA Candian International Development Authority, France, Japan, Korea, Finland, Representative of Germany, Australia.

VIDNYANACHE GAAV

A new bimonthly journal (in Marathi) devoted to issues and activities of the People's science movement. The periodical will be of interest to science lovers, people's science activists, those interested in environmental issues to all those striving to harness science for a better life. Forth coming issues — Women and Science; Environment.

Annual contribution (for six issues) : Rs. 20/-

POLITICS OF THE BIRTH CONTROL PROGRAMME IN INDIA

sucha singh gill

The myth that projects population control to be the cure-all for all social and economic problems has a class bias. According to the author the emphasis of our planners on population control is an attempt to weaken the class struggle in India by absolving the exploiters of the responsibility for perpetuating inequalities and shifting the blame from the capitalist order to the people. The article deals with two major issues in the family planning programme (i) that overpopulation is a major cause of poverty and (ii) that persuading people to accept the small family norm is the only way that population growth may be controlled. It examines the socio-political content of these issues and emphatically suggests that eardication of poverty and unemployment, and guarantees against insecurity, sickness and the death of children must be demanded as a prerequsite for accepting the small family norm.

For the last many years the family planning programme has overshadowed all aspects of our social life including the development of health services. In fact health services have been oriented drastically to suit the needs of this programme. All activities of the health institutions and their staff are subordinated to the fulfilment of family planning targets. While assessing the work of the health staff including the doctors, the only criteria has been performance in family planning work. Their annual confidential reports, efficiency bars, transfers, rewards and punishments are all based on the achievements of this programme.

The family planning programme is getting nearly as much budget as the entire health sector which contain programmes of equal or even more importance. During the 1974-79 period the health sector was allotted Rs. 681.66 crores and the family planning programme received 645.00 crores. In the sixth plan the health sector and family planning programme got Rs. 1821.05 crores and 1010.00 crores respectively[1]. Later on during the time of mid-term appraisal Rs. 68.00 crores were shifted from the general side to the family planning programme. (Planning Commission, 1983). A population Advisory Council was also set up under the chairmanship of Health Minister to keep population control under close watch and advise the government on policy matters. The 13th item of the new 20-Point Programme is specifically related to popularisation of family planning programme with the people. (Planning Commission, 1983). This renewed emphasis on the population control programme intends to achieve the long term goal of planning to reduce birth rate from 33 in 1980 to 21 per thousand in 1995 and increase the couple protection rate from 22.5 percent in 1980 to 36.6 percent in 1984-85 and 60 percent in 1995.

Although the programme is given the name of family planning and lately, family welfare, in essence it remains primarily a birth control programme. This is evident from the fact that as compared to Rs. 1078 crores allocated for family welfare programme in the Sixth Plan only Rs. 250 crores were for nutrition programmes (Planning Commission, 1980). The programme is not linked up with important aspects of future plans necessary for the welfare of each family such as education of children, their employment, security of family against sickness and old age or rehabilitation of the destitutes. There is no provision in the programme to protect the family against economic, social and psychological insecurities being increasingly generated by the socio-economic dynamism of Indian society on the capitalist path. In this situation the family planning programme remains as an intervention by the government only to limit the number of children through birth control measures.

However what matters most for individuals who plan their families is a better future. They want to improve the economic and social status of their family through education and employment of their children and accumulation of non-human assets. Both these assets human and non-human, are a guarantee against sickness, old age and destitution in addition to the psychological satisfaction. Obviously, they need a minimum number of children particularly male ones for this purpose. Nothing is done where actual planning is required and couples are left on their own, unprotected against various types of insecurities. Thus family planning or welfare programme is a misnomer and emerges prominently as a birth control programme.

The Poverty-Overpopulation Myth

The Population control programme is one of the key programmes in India. Indian planners view the

limiting the growth of population as one of the main objectives of planning. In the words of the planning commission, " it is almost axiomatic that economic development can, in the long run, bring about a fall in fertility rate. However developing countries with large population cannot afford to wait for development to bring about a change in attitude of couples to limit the size of families as the process of development itself is stifled by population growth". (Planning Commission, 1980). During the emergency (1975 77), a naked expression of this hidden message of the Planning Commission was seen. The poor people were forcibly sterilised in huge numbers and in a manner worse than animals because the government and the Planning Commission could not wait for a change in their attitude.

The success of development planning and particularly solution of major economic problems such as poverty and unemployment have been linked up with the success of population control programme. Planning Commission states, "All plan projections of reduction of poverty and unemployment will go wrong if success is not achieved in containing the growth of population". (Planning Commission, 1980)

This policy of the government to control population has a class bias (Banerji, 1971). Indian society is a class divided society. Rural and urban poor belong to oppressed classes — poor peasants, tenants, artisans, agricultural/industrial proletariat and others engaged in a number of odd jobs. These poor people have a very weak material base and are deprived of the means of production. They live on their family labour. Their greatest asset is their labour power. It is the sole source of their income, prosperity and security against old-age, sickness and other adverse circumstances. The poor people without children generally become beggars and destitutes in their old age as there is no institutional arrangement in our society to look after them. The material need of the poor to have more children is more acute as compared to the rich.

A number of studies in India show that among the poor households poverty is not caused by the large family but rather, it provides some relief against it (Mamdani 1972, Mamdani 1976, Nadkarni 1978). The poverty of the poor households originates from their poor command over the productive resources such as land and capital assets. According to agricultural census 50.62 per cent holding with less than 2.5 acres of land operated only 8.97 percent of total cultivated area. On the other hand, the top 15.17 per cent of the holdings with more than 10 acres of land operated 60.63 percent of the area in 1970-71. Almost the same trend is observed from data about 1971-72 from the 26th round of National Sample Survey (Laxminarayan and Tyagi, 1976) Land is the most prominent asset in the rural areas and it accounted for 66 per cent of the total assets in rural India in June 1971. According to the Reserve Bank's All India Debt and Investment Survey (RBI, 1971-72) 9.34 percent of rural households were landless and 27.63 per cent of the household owned less than 0.50 acre of land. According to this survey the top ten per cent of the rural households accounted for 50.56 per cent of the total rural assets (Basu 1976). The distribution for assets in urban areas is even more skewed with major part of the private corporate industrial structure being under dominant control of top monopoly houses (both Indian and foreign). Thus the poverty of the poor families emanate from their weak material base rather than family size.

In the same way unemployment in society cannot be explained in terms of population growth. It can be explained only in terms of management and development of the economy on capitalist lines. The dynamism of capitalist development produces large scale unemployment. Marx points out, "the labouring population therefore produces, alongwith the accumulation of capital produced by it, the means by which it itself is made relatively superfluous, is turned into a relative surplus population; and it does this to an always increasing extent. This is a law of population peculiar to the capitalist mode of production; and in fact every special historic mode of production has its own special laws of population, historically valid within its limits alone". Even in professional jobs like that of teachers, doctors and engineers there exists unemployment, though there are a number of illiterate persons needing teachers, sick people in need of doctors and a large number of projects needing engineers. In a capitalist economy resources are directed towards profit maximisation rather than towards social usefulness. Many resources including an unemployed labour force can be socially useful but remain unutilised for want of profitability. Unemployment is a typical characteristic of capitalist development. It is not due to high population growth. In capitalist economies there is a fundamental right to property but no such right to work.

The emphasis of Indian planners and policy-makers on control of population through birth control measures as a precondition for the success

of plan to eradicate poverty and unemployment is an attempt to conceal the basic causes of these problems. It is an attempt to project population growth as the villain of every problem in society. This tries to conceal the root cause of such problems that is unjust socio-economic systems. It helps in diverting attention from the exploitation of society being carried out by multinationals in collaboration with local monopoly (and non-monopoly) capital, exploitation of labour by capital (both in industry and agriculture), and exploitation of tenants and peasants by landlords, moneylenders and traders. It is this system of exploitation which is responsible for a shift of resources (income and wealth) from the poor to the rich and is the basic cause of poverty. The control of the exploiting classes over state power to maintain the existing system of socio-economic organisation of society on capitalist lines is the basic cause of unemployment and other problems of Indian society today.

Poverty and Family Size

Family size is the only asset which the poor possess and it provides them income and security of various types. Since the family size and from it the family labour is the mainstay of the poor, they have a greater need for children. Added to this is the fact that the survival rate of children in India particularly in poor families is low. In 1971 infant mortality rate was 129 per 1000, 138 for rural and 82 for urban areas. In 1978 Infant mortality rate was 126-136 for rural and 71 for urban areas. Inspite of the wide claims of improvements in the health services the infant mortality rate has not gone down, particularly for the rural areas, where three fourths of India's population resides. The infant mortality rate though slightly low for male as compared to female is quite high in India. In 1978 it was 120 for male and 131 for female. Data on the infant mortality rate of different income groups/classes is not available. In their absence, let's look at the data of scheduled caste/tribe. Infant mortality rate in case of these two categories is higher than the average. In 1978, it was 152 for scheduled castes as compared to all India rate of 126. Similarly infant mortality rate in the women workers is high. It was 143 for farmers, fishermen, hunters, loggers and related workers; 150 for production and related workers, transport equipment operators and labourers. (Registrar General of India 1983). The magnitude of the problem can be judged from the fact that a fourth of the children in India die before attaining adulthood. Thus the survival rate of children is low particularly among the weaker sections and oppressed classes in India.

The socio-economic dynamism of society on the capitalist path levies very meagre resources with these sections. So they cannot afford medical facilities of their own. They are denied even the shabby public health facilities available in our country. That is the reason that most infant deaths below one year take place unattended by trained medical practitioners. Percentage of such deaths was 58.3 in 1978. The state of other necessities of life needed for good health is also deplorable. In India most of the people do not have facility of hygienic and clean drinking water. Even now 57.70 percent of the people are drinking water from wells and 5.31 percent from pond/tank and rivers. Only 34.35 per cent of population drinks water from taps and handpumps. (Registrar General of India, 1983) Average calorie intake in our country is 1880 which is even less than the minimum calories needed i. e. 2250. Inspite of three-fold increase in the food grain production our per capita consumption is stagnant since 1956. The poor do not get reasonable good diet, clean water and secure shelter in life. These factors are responsible for high motality rate in the children, thus the need of the poor to produce more, in order to get a minimum number of surviving children. Even in a prosperous state like Punjab, on the average 1.10 children per family had already died when a survery of the sterilised couples was conducted (People's Health Group,)

Childern are also source of income before their adulthood. Though child labour is legally banned yet a large number of children from poor families are labourers. Both in urban as well as in the rural areas children can be seen doing all types of odd jobs to earn wages or help in family work in productive activities. According to the Government of India survey 3.7 percent of the Children were full-fledged workers in 1978 — 4.2 percent in the rural areas and 1.5 percent in the urban areas. In the rural areas 4.8 percent of male children and 3.5 percent of female children were workers. About 80 percent of child labour were children of farmers, fishermen, hunters, loggers and related workers and 11.64 percent of production and related workers, transport equipment operators and labourers. Thus children belonging to the poorest families do not attend the school - but contribute to the family income. On paper children may be shown in schools but a large number of them from poor families drop out and

join the labour market at a very early age. In addition to being full-fledged workers a majority of the children, particularly in the rural areas, contribute significantly to the family labour. It is obvious that child labour can not be stopped by implementation of legislation but through material upliftment of the poor families in the society.

Apart from these economic factors, there are a number of social reasons why people need to have more childern, particularly male ones — emotional security, social status and continuity of family, are some of them. For these reasons common people have an urge to have more than one surviving male child in the family .Even in a relatively prosperous state like Punjab where a lot of people from the villages are employed in government and semi-government jobs, the average number of children after which the couple accepted sterllisation was 4.47 with 2.48 boys. The figures for the agricultural workers was a little higher i. e. 4.54 and 2.58 respectively (The detailed break up is shown in Tables I & II.)

Only four percent of the couples accepted sterilisation after two children — the norm recommended and propagated by the government. None of the agricultural worker's families accepted to stop after two children.

Table I

No. of Children per Family in rural Punjab (percent of couples already sterilised).

Category	No. of children/family					
	1	2	3	4	5	More than 5
In general	Nil	4	22	30	22	3
Agricultural workers	Nil	Nil	14	37	30	19

Table II

No. of boys per family in rural Punjab (percent of couples already sterilised)

Category	No. of boys/family				
	1	2	3	4	5
In general	7	48	38	4	3
Agricultural workers	7	42	40	9	2

Table III

Minimum no. of children they could imagine (Boys + Girls)

Boys Girls	1+0	1+1	2+0	2+1	2+2	3+0	3+1	3+2
No. of couples (percent)	Nil	2	4	66	21	2	4	1

In this survey which was carried out in the rural areas of Punjab 98 per cent of the couples could not imagine less than two boys for a family. This survey was conducted by the family planning staff whom the villagers always want to please by mentioning the least number of children there should be in a good family. Taking into account the average loss of 1.10 children per family, one can imagine that their desire to produce 4 to 6 children or 2 to 3 boys is not unnatural.

A family without a male child is still looked down upon and parents with one male child are still considered as blind in one eye. The two children norm propagated by the government is not acceptable to people at large. These are in fact, family norms of educated middle class. It is for this class that children remain a burden to be borne by families for a considerable period in India. They have to be reared, well-looked after, educated and even helped to get a middle-class job. In this way they have to be supported for 20-25 years before they can be of economic use to the families. That is the reason most of the middle class people have been following small family norms and not primarily because of family planning propaganda. It is worth mentioning that many of the countries have never propagated family planning and still their growth rate is almost nil. For example USSR had never launched a family planning programme of the type we see here in our country. Although that government always encourages its citizens to produce a number of children, half of the couples produce only one or two children.

It needs to be **reasserted that poverty is not explained by big family size but by the weak material base or by lack of productive resources at people's command.** The link between eradication of poverty, population control and the idea subscribed to by Indian planners, that the success of the former is linked to the success of the latter, is ideological. It is not based on a scientific analysis of our socio-economic reality but rather, it amounts to consciously making the whole thing stand on its head.

The idea of projecting population growth and large family size as the basic problem of society is an attempt to hold people responsible for their problems and exonerate the ruling classes from this responsibility. It is an ideology of the ruling classes to shift the blame of existing social and economic mess to the people in general. This 'ideology of victim blaming' is being widely used by the ruling classes in all fields of life to blur the rising consciousness of people. This fact, that the poor do not find the two child norm suited to them and therefore do not accept it is used by the rulers to attack the poor, an attempt to pre-empt the attack by the poor on rich.

Birth Control Programmes : A Subtler Form of Class Oppression

The rigorous implementation of small family norm and population control on the unwilling poor leads to the use of some form of open or tacit compulsion. The officials entrusted with the task of fulfilling the targets, compel the field staff to bring enough number of cases for sterilisation. The field staff uses various means ranging from incentives of financial help to the threat of officials and local influential persons to complete sterilisation targets. Given the unjust socio-economic system, such threats work only on the unorganised poor in the country. This take the form of direct class oppression of the poor, the worst form of which was faced during emergency period of 1975-77.

Sterilisation particularly of the women has mainly become the birth control method of the poor. The side effects are multiple. One is the development of complications arising out of sterilisations and even deaths of some women. Back-ache, pelvic pain and other problems make the women chronically ill. In a survey conducted in Punjab more than 80 percent of women complained of one or more problems after the operation. (People's Health Group). This adversely affects their capacity to work and consequently the earnings of the working class families. "For women of labouring class . . . tubectomies may be a dangerous intervention, productive of family conflict and tragedy: if it decreased the women's output then children are made to do her work, while, if she is forced to keep her economic activity at the same level, children then have no protection against either the hopelessness or savagery of her feelings". (Pettigrew, 1984). Therefore, tubectomy operations are not only inappropriate but harmful to working class families. For obvious reasons, doctors, engineers, lawyers, college/university teachers or bureaucrats hardly use this method. Nobody has ever asked those recommending tubectomy to poor women as to why they do not get their own women sterilised.

In this context birth control programmes not only becomes a political enterprise but a subtler form of class oppression. It hits them hardest but conceals the identity of the attacker. It directly transmits the class conflict into family conflict among the

poor. It is an attempt to blur the class conflict and hits the poor through control of their reproductive system. By thrusting upon the unwilling poor sterlisation and particularly the tubectomy operations make the poor economically weak and psychologically shattered. This reduces further their capacity to organise and fight against their oppression and exploitation. It is a way to dominate economically, politically, culturally and socially to perpetuate the system of exploitation. This leaves them ideologically confused, socially shattered, politically weak and psychologically perplexed. This is an offensive of the exploiters against the exploited to weaken them to avert the offensive. It is a serious attempt by the rulers to reduce the number of their enemies in order to reduce the risk to their oppressive regime. It must be emphasised and re-emphasised that too small a family among the poor is economically, socially and politically a weak family and is bound to affect their class strength. Therefore, pro-people elements in the society must understand that birth control programmes are a part of the ruling class strategy of repression of the poor in general. But this is presented as a programme of welfare of the people. This needs to be exposed as a thoroughly anti-people programme which affects the very vitals of the people. It operates at a very subtle level and intends to control the most senstive part of life that is, reproductive system.

The political nature of this programme must be made clear to the people. The failure of the ruling classes must not be allowed to be projected as failure of the people. The un-willingness of the poor to accept the two child norm of the ruling classes must not be allowed to be used as a pretext to use frank and hidden compulsions against the poor. The eradication of poverty and unemployment and guarantees against insecurity of old age, sickness and death of children must be demanded as a pre-requisite for accepting the small family norm. The impatience of ruling classes to thrust birth control programmes on the poor even with coercive methods before even attempting to solve the socio-economic situation which make a large family desirous needs to be understood and opposed. The only check against this on-slaught is through the conscious organised force of the poor.

Just Out

The Political Ecology of Disease in Tanzania
by Meredeth Turshen

Rudgers University Press Diotribution Centre, P·O. Box 4869 Hampden Station, Balfimore MD 21211, USA,
25 dollars

The book looks at disease in Tanzania and argues that it is not the inevitable consequence of climate or geography but the result of colonialism and capitalism. Colonial rule changed the ecology and economy of the country, imposing frontiers that did not respect African settlement, bringing in new diseases, and starting wars of conquest that touched off epidemics. Women were particularly affected — their social position was lowered, their political power was eliminated, and their role as valued food producers was lost. After 1961 the new government tried to meet the basic needs of its people, and on some levels it achieved a measure of success but certain programmes, like the reorientation of the system of food production, were unsuccessful.

CONTRACEPTIVE RESEARCH IN INDIA

Testing on Women

kusha

Field trials to determine the efficacy and safety of a particular contraceptive are very often carried out in a dubious manner in the third world on women from the deprived sections of society. Research institutes are either coerced or tempted by international funding agencies (sometimes through the government) and are used as laboratories to test out potentially dangerous contraceptives The author relates her experiences in a contraceptive testing unit (CTU) located in the working class area of central Bombay. Inspite of visible side effects, contraceptives ranging from diaphragms to hormonal implants to injectable contraceptives as well as new drugs to induce abortion (MTP) were tested on women in exchange for a modest monetary incentive.

Introduction

Family welfare programmes have to be committed to the emanicipation of women and their being accepted as equal partners in decision making in all spheres of developmental activities. International women's year has created a widespread awareness of the inequalities between men and women. It threw light on the steady decline of women in the labour force, and on the poor participation of women in socio-economic and political activities. The report on the status of women brought out the urgeney of providing facilities for training women and to provide an opportunity for their access to sources including tools and skills so that they could enhance their contribution to their family and to society.

In the field of family planning, it is important to understand the acceptability of a particular contraceptive, reasons for choosing one method over the other and assess what makes women and men continue or discontinue using a method of their choice. It is also important that family planning education is given to both men and women emphasising the inter-relationship between family planning and the status of women, since it is a recognised fact that the status of women directly influences the acceptance of family planning. At the same time the availability of family planning education directly contributes to the status of women by conferring on her a basic human right to choose.

The term 'family planning' was changed to 'family welfare' on this basis and entirely on the premise that when an eligible couple is contacted for family planning, it is the 'couple' who equally share the responsibility of deciding the type of contraceptive they will use, the number of children they will have and when to have them. What is generally happening in reality in the field of family welfare is just the opposite. The ideal contraceptive, acceptable to all people from different strata of society, at the same time being harmless, effective, easy to use, easily available and cheap simply does not exist, at present. What is more disturbing is that research towards attaining this ideal is also not given priority.

Goverment Policies

The initial approach of setting up clinics in different parts of the country and waiting for people to accept fertility regulating methods (FRM) was based on the several so-called (KAP) studies which indicated family planning acceptance. However, the policies of the government changed from time to time due to pressures from foreign government and non-government agencies mostly from the west since these agencies provided money and aid in kind. Later, the approach was changed to family planning extension programmes wherein family planning workers moved in the community and set up depots to distribute condoms. However targets were not fulfilled and once again the approach was changed. Family planning was then integrated with maternal and child welfare programmes and in 1966 post-partum programmes were launched.

These changes of approach were only made on the basis of whether targets were being met or not. For instance at first the number of conventional contraceptive users was considered; the number of IUD users was counted without any consideration of the removal rate after IUD insertion and so on. The same was true with pill users and the extent of bogus sterilisation is only too well known. The KAP studies were mostly useless because the ethos, needs or priorities of the people was not considered.

Added to this in several states the government in its enthusiasm to achieve targets bungled their programmes by coercing people to accept IUDs or sterilisation operations.

The state governments got away with this callous approach to meet targets as far as women were concerned. Women were made to suffer humiliations, indignities and often serious physical side-effects, but the strategy boomeranged on the government when men were forcibly sterilised. A government was toppled! Even then this patriarchial male-dominated society did not care to understand what suffering women had been made to undergo for so many years. If women complained they we e told to bear the side-effects. Now during the past few years, probably to pacify the male ego and to stay in power, the government's stress is once again on women—catch them anywhere, in hospitals after delivery or in abortion and child welfare clinics. Women have to accept any contraceptive that suits the authorities.

Review of literature

Dr. D. N. Kakar has done a study of women using either the pill, IUD, or injectables Kakar, 1984). The study throws light on several factors responsible for a method being continued or discontinued. It is strange why a similar study was not done on the use of condoms. It is because men cannot be bothered to accept the responsibility of using this method ? Though Dr. Kakar's book deals only with women's contraceptives, it sheds light on several important factors which are directly connected with physical problems faced by women due to contraceptive usage and male attitudes to contraception. In several case studies it was pointed out that women discontinued contraceptives because of side-effects such as spotting or intermenstrual bleeding. Several women said that they needed much greater medical attention when these side effects took place. They needed reassurance and understanding from their husbands but were instead treated with a certain coldness Dr. Kakar asks, "how many husbands would be genuinely concerned about providing comfort to their wives without being able to derive sexual gratification ? " It is usually the woman who bears the brunt of physical discomfort and at the same time takes the responsibility of avoiding a pregnancy.

Annual reports of the Indian government and many of the western offices of population have shed light on the amount of foreign aid in the nature of cash and kind. The main contributor to the population control fund and even to the concerned UN body is the USA. The UN has set up a special division on biomedical research and over 100 million had been spent by 1972. The division has clinically tested 45 different drugs and six different devices on 45,000 persons — mainly women of the third world. Among those who have been funding the population activities in the third world countries in cash or kind either through the government or through private agencies are US, UK, Netherlands, Japan, Germany, Canada, Norway and Denmark. In India, WHO and Ford Foundation are the major contributors for research in contraceptives. IPPF, Pathfinders and Population Councils are other important donors. By 1980 over 7,500 subjects, mainly women in Bombay alone were involved in some of the trials in contraceptive testing.

Historical background of a contracptive unit

The family planning unit of the government of India was started in 1954. It had three main objectives - (i) testing of contraceptives for their efficacy, safety and acceptibility; (ii) conducting research in reproduction and fertility control; and (iii) developing newer contraceptives. In 19 6, the FP unit was reorganised as a contraceptive testing unit (CTU). The first clinic was set up in the industrial area of central Bombay. Located in the premises of the mother and children welfare society, the health of mothers and children formed an integral part of its work from its very inception. The social workers' attitude then was to educate women and men of the community in every facet of health. Stress was laid on the overall education of people through organising the community around the clinic. Men, women and children came to the clinic not only for FP methods but for all their socio-economic and other personal problems. Some of the activities started at the clinic were (1) Education of men and women and children through exhibitions, group talks not only on FP but also in health care, antenatal care, post natal care, women's movement and nutrition education. Women and girls were given sex education. (2) The entire community was screened for TB by taking mini x-rays and treated or referred for admission to a hospital. (3) To get the entire community involved in the welfare activities, health day, 'makar-shankranth' day, children's day, women's day and so on were celebrated. (4) Women were encouraged to speak in meetings and debates, their mahila mandal was set up and skits and songs were staged by the women themselves. Competitions in essay writing, painting, were held. Classes in first aid, nutrition and adult education were conducted. (5) Efforts were made to help women continue education and to

secure jobs. (6) Even separate clinics were conducted for ANC and PNC as well as for babies. Sterility being a major problem of the community, sterility clinics were also conducted.

Research activities

Between 1958 and 1962 it was found that older women with large families were the only ones who were attracted to the clinics. As welfare activities increased and as more welfare clinics were set up in different parts of the industrial area in central Bombay a larger number of younger women began to attend the clinics. Foam tablets, spermicide jellies and diaphragms were the conventional contraceptives available at that time. Each woman attending the clinic had to undergo a test for PAP smear' and colposcopy examination to rule out cancer and other gynaecological complaints before contraceptives were given to her. Field trials on foam tablets were conducted. Several foam tablets like Contab and Planitab, were tested. The CTU developed a "24-hour CAP test", to assess the harmlessness of foam tablets and contraceptive jellies Several batches of foam tablets and contraceptive jellies received under a code number were tested by this method which was standardised and recognised internationally. When several jellies were d squalified, there was a hue and cry by the pharmaceutical companies manufacturing these jellies. They pressurised the CTU to abandon the test but the CTU was firm and this rigid stand taken by the unit prevented the release of these sub-standard contraceptive jellies into the Indian market.

By now there were six clinics, three being in industrial areas, two attached to hospitals in Bombay and one in a rural area attached to a PHC In the first year of their existence the community had accepted these clinics truly as family welfare centres. There was an excellent rapport between the research staff and the family members. Those who participated in research trials knew fully well the implications involved. With the arrival of IUDs and later the hormonal pills welfare activities were curtailed. The government started thinking in terms of cost benefit for the entire FP issue. No funds were released for activities which were meant for the welfare and education of the people.

Women were offered money for participating in research. The health of women did not remain the prime consideration of these centres. Several types of IUDs were tried. Now with education, younger women had started attending FP clinics for spacing their children. Eminent gynaecologists based in Bombay made some modifications in these IUDs. Comparative studies with different types and sizes of IUDs were conducted to find out the ones that had minimal side-effects and low failure rates. Copper T and Lippes loop are the outcome of this research and both are now extensively used by women all over the world.

In 1958 and 1959 Dr. Gregory Pincus introduced hormonal contraceptives. The CTU at that time was asked to introduce in their field trials 10 milligram doses of this hormonal contraceptive. This move was resisted by the social workers as they did not want to endanger the health of Indian women. During the sixties and seventies, the government accepted lower doses of hormonal contraceptives for trials in our country. Then began the exploitation of women in contraceptive research.

In the field of research, the funding authorities selected their own research scientists, institutes and private agencies to carry out the research in what they believed was the important area. Policy decisions were also in their hands. What we see today, therefore, is that contraceptive research is being conducted in the area of "someone else's" choice. No research is being done to evolve safer mechanical barrier methods, neither to improve the efficacy of the older methods nor to evolve indigenous safe methods. The mode of administration of hormonal drugs, the dose and the content have varied. But they still remain the dreadful hormones tampering with the woman's body. Listed below are some of the contraceptives, in which research trials were conducted :

Foam tablets : These are used by women just prior to coitus A wet tablet is inserted in the vagina releasing foam which acts as a screen against penetration of sperms which are killed by the chemical action. The women's cervix and vaginal walls could be affected, resulting in irritation, burning and white discharge for many. Efficacy is around 40 per cent.

Diaphragm and jellies - or jelly alone : Spermicidal jelly is applied to the diaphragm and inserted in the vagina within an hour before coitus. The diaphragm acts as a mechanical barrier and the jelly destroys the sperms. Efficacy is good, but this method requires privacy and facility for washing. As above, the cervical canal and the vaginal walls are affected and may cause irritation, burning and white discharge.

Intra-uterine devices (IUD) : There are several types and sizes of these devices— the

important ones being the Lippes' loop, maxguli coil, CuT, CuY, Sonawala and Merchant's devices, and others. All these are inserted within four to seven days of menstrual flow. Being a foreign body inside the uterus, changes in endometrium and release of chemicals occurs resulting in cramps, irregular bleeding, perforations, white discharge and abdominal pains. Some women also complained of headache due to copper devices. (Interestingly when a Lippes loop was inserted headaches disappeared) Unnoticed expulsion is another problem. Perforation with IUDs are well known and the whole of the abdominal cavity could be affected.

Oral pills : Hormal steroids are the basis of each pill. The woman has to swallow one pill a day for each day of the month (with a gap of seven days or otherwise depending on the type of steroids). There have been three-a-month pills too. These gave woman a severe bout of vomitting, giddiness and headaches. Women complained of headaches, nausea, giddiness, dizziness, weight gain, weight loss, rise in blood pressure, continuous bleeding or intermenstrual spotting. Pills have adverse effects on liver function, immune response of the body and cause vitamin B complex deficiency. The oral pills either inhibit ovulation or bring about changes in cervical mucous prevailing pregnancy. Drop out rates are very high.

Injectables : There are two types of injectables, injection Depoprovera and injection NET-EN. Both are known for their adverse effects. These are given to women either once a month, once in three months or once in six months depending on the dose of steroids. Those women who were given 300 mgs (once in six months) after delivery continued to have bleeding severe or moderate to spotting daily for over four to five months. Woman developed prolonged ammenorrhea (absence of menstrual flow). The drop-out rate was very high. Although injection Depoprovera was withdrawn by the government on hearing of the dangerous effects private agencies even today are promoting these through their outlets in India as well as in many other third world countries. Once the injection is given it cannot be withdrawn and the woman has to suffer as long as the effects of the injection persist in her body.

Implants : These are silastic subcutenous implants introduced in women's thighs. The hormones are slowly released into the blood stream and act to prevent conception. Those tried in the CTU clinics were supposed to protect women from pregnancy for eight months but the majority of subjects become pregnant within six months. Side-effects are same as those of hormones. Women had to undergo minor surgery for removal of empty implants which would get embedded in the muscles.

Vaginal rings : These are inserted in the vagina on the fifth day of the menstrual period. It is removed only at the next menstrual period. The vaginal rings are absolutely useless for the majority of women who have no proper toilet facilities. But they were being tried for the prestige of an individual scientist. The vaginal ring caused irritation, burning in the vagina and white discharge. It would also slip off and get lost.

Nasal spray : This drug is dangerous and useless for the majority of our women. It could affect the nasal cavity, thalamus, brain and even the heart as the woman is expceted to spray the drug daily through her nose in definite quantities. Poor malnourished women were cajoled into participating in this trial.

In all the hormonal drug trials women were required to give blood samples at definite intervals to assess the release of hormones in the blood stream. As many as 80 blood samples were collected in some of the trials. At least 10 to 15 blood samples required to be given by each woman participting in each of these trials. Not one lady medical officer has ever raised her voice in protest against this exploitation of poor women. Medical officers are more aware of the hazards a malnourished woman on these trials had to undergo. Yes, women were paid for participating in these trials. But that did not mean that these women had been bought that they could be used as guinea pigs. Are the women doctors so inhuman as not to understand the gravity of the situation ? The health of poor woman is being sacrificed for others — mainly for those funding nations and agencies and in order that the elite may know if a contraceptive might be dangerous or not. Few middle class or upper class women will agree to participate in such trials.

Research in male contraceptives

Mention has to be made of Dr. Padma Vasudevan who has used her knowledge in polymers for evolving a new method of contraception for use by men. Condoms and vasectomy operations are so far the only two methods for men, condoms being the most harmless and the easiest to use.

Dr. Kothari of the KEM Hospital has also conducted some research on developing intravas device (IVCD). But Nothing has been heard of this research for some time now. Nasal sprays were also to have been tried out on men. It is reliably learnt that although men were being approached for trials, not a single man could be enrolled for this trial inspite of being offered VIP treatment. Men apparently could never be bothered with any such trivial contraceptive research trials !

Birth control methods under trial

(a) **Morning after pills :** Trials with 'Morning After' pills are in progress. These are hormonal pills to be swallowed by women the day after coitus. It is too early to say what the side-effects it may have. Women on this trial are also required to give a number of blood samples.

(b) **Pellets :** These are expected to arrive soon for trials on Indian woman. It is not yet known as to which part of the woman's body will be tampered with this time.

(c) **Vaccines :** These are also expected to make their way into India. These vaccines will affect the outer covering of the ovum making it impossible for sperms to penetrate and for fertilisation to occur.

(d) **Prostaglandins for abortion:** When a woman desiring abortion (MTP) goes to a hospital she cannot choose the method by which she will be aborted. Even though there are safe methods which could be improved by research, a drug prostaglandin is being tested. This drug not only gives the women severe camps, abdominal pain, vomitting and diarrhoea but in some cases was the cause of incomplete abortion. Women under the trial programme suffered tremendously. This is another case where advances in science are also being used against women. Amniocentesis was a method developed to help detect an abnormal foetus yet it is now being used extensively for sex determination of the foetus which has in turn led to sex selective abortions.

From the CTO Records

Women of India, mainly from the weaker section of society, are being subjected to all kinds of inhuman treatments at home and even in places where they expect help and service. The following are a few instances recorded in the clinic which illustrate the attitude of husbands towards the wife vis-a-vis her reproductive responsibilities.

Case 1 : During the late 1950s, the early years of the FP programmes, foam tablets as contraceptives were being offered to women. A mother of five children accepted this method after consulting her husband. A packet of 12 tables used to be issued whenever she wanted the stock. Once, a clinic staff removed one tablet from the pack to test the foaming capacity of the tablet and issued 11

(Contd. on page 178)

Campaign Against Long Acting Contraceptives

The government has decided to allow family planning institutions and private gynaecologists and obstetricians to import the injectable contraceptive, Norethisterone enantale (or NET-EN). The ICMR has been conducting studies on the drug for some time now under the WHO multicentric trial programme. The report of the study has not yet been made public and components of the study have not been completed as yet. NET-EN is a synthetic progestogen, similar to Depo Provera which has been the centre of a raging controversy among experts regarding its safety and suitability for women. Several women's groups, people's science groups and people's health groups have come together to protest against the introduction of NET-EN or any other long-acting contraceptive, such as Depo-Provera or contraceptive implants. The demands of the campaign are : Ban NET-EN; Ban all injectable contraceptives; All exports of the ICMR and other studies should be made available to the public; A public inquiry and debate must be instituted before such controversial contraceptives and drugs are introduced into the country. The campaign group's first action was a demonstration at the closed-door experts' meet convened by the Family Planning Association of India ostensibly to help make the decision on whether or not to use NET-EN and/or Depo Provera. The demonstrators distributed pamphlets and stated their demands to the assembly. Sympathetic participants later disclosed that discussions had centred around how best to use the injectables and not whether or not.

For further information on the campaign, please write to Women's Centre, Yasmeen Apartments, Yeshwant Nagar, Santacruz (E), Bombay. So far the following groups have decided to participate in the campaign—Women's Centre, Forum Against Oppression of Women, Medico Friend Circle, Committee for Protection of Democratic Rights, Shramik Mukti Morcha, Kashtakari Sanghatana, Yuva Sangharsh Vahini and others.

Response

Dear Editors : I would like to begin by congratulating Ilina Sen on a principled stand from which many women withdraw feeling that it is not worthwhile raking up a lot of muck. With the result that we continue to be invisible and inaudible. It is important that women emphasise their contribution and insist on recognition if certain deeply ingrained attitudes and assumptions are to be rooted out.

As for Dhruv Mankad's reply - if it had ended with the first paragraph it would have been excusable. Even there - there is the implication that among all the people listed to who contributed to discussion there was no one else who chose to make such a fuss over nothing. It is also astonishing that an editorial perspective is produced without actually reading the articles referred to. I will not raise questions of thoroughness (marxist or male) for fear of being labelled ignorant and presumptuous. Let us just look at the rest of the reply. It is so typical that it merits some examination. A perfectly legitimate protest is called "petty" and "unprincipled", *because the misunderstanding is not sorted out in private*. When such attempts are made in private, our experience is that the jokes which are the normal response deprive it of all seriousness. Secondly the "allegations" are called "wild", the reasoning "immature" and the presumptions "incorrect". This leads to "bickering and quarrels". All this is old hat. Whenever a woman protests about such omissions - the assumption is always that the basis is emotion, hysteria, imbalance and irrationality. The old myths about what the ovaries can do ! Finally after all this heavy-handed, high school masterish chastising of such infantile behaviour Dhruv Mankad actually says he is restraining himself. This is admirable. I for one am really curious to see what his less restrained public behaviour is like. Finally of course the accusation that such reactions are not "responsible". I think it is time we began to examine our own reactions a little more responsibly and critically. It is ironic that in an issue on **Women and Health** such stereotypical reactions should be produced. When I mentioned my own angry reaction to a friend the response was that such debates would not do the magazine much good. On the contrary many of us feel it is far better to discuss these things frankly and openly and expose our own weaknesses, so that we can make a beginning towards recognising and dealing with them. For too long now, the questions raised by women have been subsumed to a larger good, be it the Family or the Cause. Perhaps it is time at least when we are talking about how medicine has rationalised Society's and Men's notions about women we begin to question our own.

May I say how much many of us have looked forward to and enjoyed both the issues of Socialist Health Review ?

Vasantha Kannabiran

Dhruv Mankad replies

I agree with Vasantha and Ilina that generally a woman's contribution is, consciously, or unconsciously ignored and that whenever she protests against this, it is rejected as hysterical. I also accept that, generally men, including myself, do have conscious or unconscious patriarchal prejudices, having been under their influence for many generations. But in this particular instance, neither in the 'lapse' nor in the response to the 'protest', were these prejudices at work.

I do not call the protest 'petty and unprincipled' because the misunderstanding was not sorted out in private, as Vasantha seems to have assumed. Nor do I call it unprincipled because the protest was not based in principles (which of course, it was). I call it that, because it was not carried out in a principled manner. To me, a principled way of protesting when a lapse occurs on the part of a comrade (I hope Ilina grants me that status), is for the purpose of correcting this error, not just to denounce his/her weakness in strong terms. If that is so, then one does not proceed to accuse the comrade of anything without **first** giving him/her a chance to explain whether it was an error at all, and if it was, under what circumstances it was committed. I think I have tried to point to this in my response. I felt that Ilina should have given me a chance to explain -in PRINT, not in private.

Regarding Vasantha's objections to the terms that I have used in my response viz., 'wild allegations', 'immature reasoning', 'incorrect presumptions', I can only say that I do now realise that these are the very terms about which women are— and ought to be — sensitive about. I did allow my own sensitivity to be blurred by anger.

By all this, I do not claim that I am completely free of patriarchal prejudices. But I am unable to accept any trace of 'stereotypicity' in this particular instance, where in the first place I was not directly responsible for the original lapse.

Finally I do wish to ask Vasantha as to how she came to the conclusion that I have implied that

no one among those with whom the article was discussed has made "such a fuss over nothing". The line in question (of my response) merely states a fact regarding how I came about the content of the article by Binayak and Ilina and that's just what it is supposed to mean.

Dhruv Mankad

Working Editors Reply : We believe that much of this debate would have been avoided if, in the first instance, we had explained how exactly we produce each issue. We do so now especially in reply to Vasantha's query about how an editorial perspective can be produced without actually reading the articles referred to. The editorial perspective for each issue is written and circulated among the editorial collective months in advance (for instance, the editorial perspective for the June 1985 issue was circulated sometime in November, 1984). Articles are 'commissioned' with the perspective in view and in consultation with the author of the perspective. The collective is supposed to send their comments to the author, who incorporates them as s/he sees fit and sends us a final draft for printing. Given the geographical distances, it is not possible for the author of the perspective to read all the articles to be published in the issue, although the contents of each are generally known. The Working Editors in Bombay then add to the perspective, an introduction to the issue containing short synopses of the articles. This is how we worked in producing the first issue as well. Unfortunately, given the fact that we were, at that time trying to accomplish unfamiliar tasks and had to face an array of 'teething troubles' in producing that first issue, we did not check either the copy or the proofs as accurately as we ought to have. Hence the ommission of Ilina's name in the perspective. (with which Dhruv had nothing to do). After having produced four issues, we are now a little more confident and better organised and are careful about checking everything closely. But if there are ever such lapses, please bear with us. Please be assured that we will endeavour to see that prejudicial bias, of any kind, conscious or unconscious, is not projected through SHR.

Dear Friends: Your editorial (SHR I:2) speaks of health organisation as some sort of minimal structure for the poor (working classes), just to keep them from being unproductive to capital. Perhaps your analysis is correct for India (but even there you should think more on the social role of the hospital and the whole gigantic structure of the health institution), but it is not correct and could be misleading for 'capital' as such (which would include industrialised countries as well). I think in our countries (in particular Switzerland) the health institution has been growing to gigantic proportions - - providing a well-defined and reductive sort of 'health', but providing it all the same --- because of the powerful interests that are gravitating around it. It would be the same for a television production capital, an etertainments producing capital, and so on. All these, health included, are capitalistic commodites and lead to profit and accumulation. In the same way as you make money forcing people to go in for colour television (the advertisements are increasingly directed at the working classes) and for personal computers (Spanish and Italian immigrant parents here seriously think of investing 4,000 to buy one for their 14-year old boy), they make money by sending people to ever-growing numbers of hospitals and giving them an increasing number of drugs. Thus the model presented should be more elastic and realistic and try to rouse people about the lack of medical care as well as the profit aspect of this care.

I dislike very much the statement that "women can relate only to other women when it comes to health and their bodies because only women can truly unlerstand one another's problems' (SHR I:2, 66). It is unmotivated, purely sentimental, imported from liberal (or radical) not marxist feminism. Should a worker in the industry were to say that he cannot 'truly understand' the exploitation of a poor peasant, what would you say ? It would be a pity to give emahasis to a thinking that separates what should be united (working class) and unites what should be separated (rich, middle class from poor women).

The paper on amniocentesis is vague and uncertain (at least in its wording which is often ambiguous). Sometimes it seems to say that the reasons were medical (deformations, and so on) but that the social context made it a real danger to female embryos; and sometimes it seems to say that it was introduced to help the massacre of female embryos. A more careful wording (and perhaps thinking) could help the reader find a way to action without being misled.

We found the paper on the Bhutali phenomenon very important and well-written. But we lack the background for understanding what 'adivasi' means for instance, The paper does not help in understanding the relevance of the phenomenon (are there a few villages or some thousands in this situation Does the phenomenon occur a few times a year or several thousand times a year ?) If you would like your journal to be read in the world could you please define terms such as adivasi, lakhs and so on ?

Dr. Bruno Vitale

Adivasi : aborigines; lakh : one hundred thousand. —W. E.

MOTIVATION FOR FAMILY PLANNING : A Short Critical Review

ilina sen

An important component of the family planning programme of the sixties and the seventies was motivation which meant planned efforts to persuade the public accept the small family norm as well as the particular method of birth control. This concept of motivation became important particularly in the mid-sixties and several strategies were evolved and implemented over the years — mass education about family planning, mass mailing schemes and the use of incentives and disincentives. The article takes a critical look at these strategies, the social political background which gave rise to them, their implementation and effectiveness. The author further examines the assumptions on which the entire motivational strategy was founded and finds them inadequate and full of deeper fallacies.

Among social development plans of the government in the years since independence, thefamily planning programme has perhaps received greater funds and attention than any other single programme. A central element of the family planning programme. as it evolved in the sixties and seventies, was its attention to motivation. By this was meant conscious and planned efforts to influence the public to accept (a) the small family norm, and (b) a particular method of birth control among the many available. In this paper we will attempt to understand this phenomenon of motivation for family planning in greater detail. We shall do this with reference both to actual strategies adopted for motivation in the period before 1977, (a year which marks a watershed of sorts in the history of the Indian family planning programme), and with reference to the theoretical and intellectual basis on which these strategies were founded.

Motivational Strategy — What It Consisted of

The Indian family planning programme was developed in response to what the planners perceived as the 'population problem'. Briefly stated this meant that they saw a high rate of population growth as a major road block on the path to planned development and had visions of the gains of Industrial agricultural growth being swallowed up and reduced to nothing by the growing number of hungry people. Family planning was always an euphemism for a policy of population control and a euphemism based on the faith that the surest way to control the rate of population growth was to get individual families to 'plan' their (small) size, which in any case was in their own interests. In the first decade of independence, the approach to family planning, as to much else, was relatively relaxed. While family planning was designated as a key sector in policy/plan documents, the adoption of specific family planning practices was left for the individual couples to decide upon. The state made available at health care centres, a variety of alternatives in birth control under a cafeteria approach.

The result of the 1961 census showing a decennial growth rate of population that was markedly higher than that of earlier decades (population growth rate was 14.23 percent in the period 1931-41, 13.31 per cent in the period 1941-51 and 21.64 per cent in the period 1951-61) brought on the first signs of panic. The FP bureaucracy felt the need to be radical, and the strategy of community motivation was among its most radical innovations.

The concept of motivation gained importance in the family planning programme in the years following the 1962-1963 report of the Director of Family Planning. This report, known popularly as the Raina Report (1963) seriously questioned the clinic type of family planning services that were then available, and under the broad heading of 'extension approach' laid down the basis for a new strategy, relying on community motivation. It recommended the positioning of an extension educator at each block who would educate and motivate people to become FP acceptors. Hard on the heels of this report, in 1965, came the the IUD breakthrough. All, it seemed that was needed to curb the population growth rate was to (a) motivate the people to have fewer children, and (b) insert IUDs. In 1965 also occurred the first evaluation study of the FP programme by the Programmes Evaluation Organisation (PEO) of the Planning Commission (1965). Following this spate of activity, PF was separated completely from health and established as a separate department. United Nations team that evaluated the programme at the request of the government (UN, 1966) in the

same year spoke optimistically of the education of the public, through opinion leaders, satisfied customers and all available types of mass media. The Mukherjee Committee on IUCD (1965) urged for a mass publicity and communications wing for the new department in addition to the army of staff recommeded by the Raina Report. One of the first results of this decision to go in for mass motivation was thus, a fantastic expansion of the Department of Family Planning. The staffing pattern recommended visualised a Block Extension Educator (BEE) at each of the over 5000 Primary Health Centres, assisted by male FP workers, and female ANMs covering 20,000 and 10,000 population respectively. Full and part-time paid voluntary workers were also employed (numbering over 75 000), in addition to extension staff for the urban clinics. However, in later years, the Kartar Singh Committee was to acknowledge that the actual coverage of extension educators had remained much lower.

The motivational strategy consisted of a massive educational programme supplemented by the field work of the extension educators who directly motivated eligible couples. The strategy for mass education was to flash continuously a few "meaningful and understandable" messages to the public such as "Do ya teen bachhe bas". The country was simultaneously plastered with the red triangle of family planning. This simplistic approach often had no real relevance to the life situation of the public that was being educated; for instance, the slogan "do ya teen bachhe bas"; was cut down to its present size from "do ya teen bache bas; doctor ki salah maniye", when it was discovered that the average Indian villager had no doctor to consult. Films, radio "traditional media," were all used for educational purposes, and although the degree or support to the programme from the mass media unit of the Ministry of Information and Broadcasting, was impressive, the contents of these media products, were unimaginative and often reflected the upper class bias of the producers and of the programme. A lot of the propaganda was centered around a stereotype of two families, the large family is always shown to be poor, unhappy, rural, dark and desi. The other familly, urban, middle-class and westernised is, needless to say, the small and happy one (Banerji, 1971). Songs were written and sung about FP by famous playback singers. FP fortnights, contests and exhibitions were organised in remote small towns and magazines were encouraged to bring out special FP supplements.

In 1969, was started the Mass Mailing Scheme. This mailed suitable informative literature directly to opinion leaders from all walks of life. Even though research found a "good" response to mass mailing, no precise indications regarding the outcome of this expensive exercise are available.

These remained the main prongs of the motivational strategy throughout the sixties. However, from the late 1960's, two parallel but conflicting trends are visible in the programme and its strategy for motivation. The painful realisation around 1968, that the IUCD had failed to deliver the goods, intensified the reliance on sterilisation; if necessary by coercion At the same time some rethinking took place on the whole issue of community motivation. In practice a "hard" and a "soft" line of action are discernable, and these can be followed up separately for convenience.

The 'hard' line :

IUCD insertion figures came down from 909, 726 insertions in 1966-67 to 478,73 in 1968-69. In hindsight, it appears that there could have been many reasons for this perhaps the natural limits of demand had been reached. However, the interpretation put on this trend by the planners, was that there were shortcomings in the motivational efforts. Community motivation being carried out at great expenses, was not having the desired results. This realisation led to the adoption of cruder measures.

Incentive for sterilisation or IUCD insertions have always been spoken of in official family planning circles as "compensation for wages lost." The 1965 Mukherjee Committee report, had spoken of paying compensation to IUCD acceptors (Mukherjee Committee, 1965). While perceiving tne danger of malpractices that may result, this was thought to be less than the danger that would threaten the programme if compensations were not paid. Compensation was tried on a small scale in some states, for instance Madras, in the 1950s, and was started on a national scale in 1964. The motivator's fees that went along with compensation was admissible not only to private citizens but also to Government Servants including FP workers. Rates of compensation were graded as being higher for sterilisations, and lower for IUCD insertions The rates were revised in 1965, and again in 1966. Incentives and target orientation of the programme led, in the late 1960s, to an increasingly greater emphasis on sterilisation with growing tendency to using coercive methods, in addition to widespread malpractices because of the system of the incentives. Any attempt at cutting down on compensation / incentives was however, strongly resented by the medical FP staff,

The idea of using disincentives finds expression in the 1970 document entitled "Master Plan for total Health Care in rural areas" (GOI, 1970) which fortunately, was never implemented. This advocates the professional access of the FP acceptors to all health services The first non-birth incentive scheme was begun by the United Planters Association of South India (Upasi) in selected tea estates in the Nilgiris under the consultancy of Doctor Ridker of USAID. Female tea pickers who had enrolled had a monthly deposit of Rs. 5/- made into their retirement benefit plan by Upasi as long as they did not get pregnant. Specific amounts of the total sum were forefeited in case of pregnancy.

The first mass vasectomy camp was held in the Ernakulam district of Kerala in 1971 (Kumar, 1972). A very large number of sterlisations were performed during the camp duration. The camp and the district collector who had organised it were hailed in FP circles in India and abroad Such camps were held in subsequent months in several other states, and they were all marked by certain special features. Higher than usual rates of compensation were given in cash in addition to gifts in kind during the duration of the camp and the entire administrative machinery of the government of the area was mobilised for publicity and organisation work during the camp. The Kerala camp also happened to coincide with the leanest agriculture season, when special incentives such as a week's extra ration took on a special significance. The demographic quality of those sterilised in the camps was never properly established by independent authorities and in any case the attendance at such camps fell off after the 1972 Gorakhpur incident in which 11 persons died of tetanus, following vasectomy. The camps were discontinued shortly thereafter.

The declaration of the Emergency in June 1975, brought the family planning programme to the forefront of Indian politics The subtle coercion used earlier was now exercised openly to promote sterilisation. Perhaps the turning points was the announcement of Sanjay Gandhi's 4- Point Programme later in 1975, in which FP played an important part. (FP had not been mentioned in the 20-Point Programme.) Sterilisation figures picked up massively—2.5 million operations were performed in 1975-76 as against 1.36 million in 1974-75 and only 0.9 million In 1973-74.

The growing panic at non-performance in a topheavy programme finds its culmination in the National Population Policy of 1976 (Singh, 1976). Though this document did have some developmental content, for instance, stress on female education, only its most coercive aspects were put into effect The policy graded incentives according to the parity of acceptors, and advocated disincentives for government servants not practising FP. Compulsory sterilisation was left to the discretion of individual states as the centre lacked the infrastructure to put such a policy into effect. However, to prod the states into activity in this regard it was stipulated that in all matters of aid allocation to the states, the 1971 population figures would be followed till the year 2001, and that eight percent of the total central aid would be specifically linked to performance in family planning In the prevailing political climate this was interpreted by most of the states as a clear directive, and the states vied with one another to fulfil targets, and to give an impression of success. In many states, departments such as police and education were used to mop up people for sterilistation, and states like MP and Bihar, fulfilled the annual target for sterilisation in less than six months of the year 1976-77. One state, Maharashtra, actually passed the bill on compulsory sterilisation, and this was only prevented from becoming a law by the grace of the President. The political consequences of these events are only too well known.

The soft line :

The "softer" trend in the programmes of motivational efforts, the carrot that accompanied the stick, remained much less effective, often amounting to a lip service only to liberalism and can be traced from the same period as the beginning of the "hard" line. Like the hard line, the 'soft' line was prompted by the realisation of failure.

Doubts began to be cast on efforts to motivate from about 1970. In that year the, second PEO report found the contacts of the FP staff with the local community to be limited and felt that "carrying the messages of FP to the village people required a knowedge . . . of their . . . norms, values, and experiences." (PEO, 1970 , Some of the pioneering writings on population, for instance that by Mamdani, had already pointed out that a large number of children may be an asset in certain class/production situations, and that in these situations it was unrealistic to expect that people would adopt the small family norm merely because a well intentioned department advised them to do so (Mamdani, 1972). It was also perceived that high fertility had a close

relationship with high levels of infant mortality, and in general, with low levels of development. The PEO report briefly acknowledges these trends when it says that "the desire for a small family is more due to economic reasons rather than due to changes in social norms." (PEO, 1970). No concrete approaches in this direction are however, suggested. Similarly, in 1969, the UN evaluation of the programme complained of "gap in our knowledge of the motivational process" (UN 1969). All the soul searching led to a few "changes and departures" in the programme's strategy to motivate the people, and these can now be taken up.

The fallacy of developing FP in isolation from health was realised, and in 1968, maternal and child health services were integrated with immunisations to children and the theme of reduced infant mortality used to establish contact with eligible couples and to motivate them to accept FP. Since however, this was also the period of targets and incentives it is doubtful if this led to any real changes in the approach or not. Possibly it only meant that the already harassed staff were overburdened with finding time for MCH and that these services actually suffered in consequences. The post-partum programme was launched in 1969 in selected hospitals in the country on the basis of the following philosophy: "the months following delivery or abortion... are significant periods of high motivation during which women can be approached concerning future child bearing". Since however, the actual number of hospital deliveries in India form so insignificant a part of the total, the demographic impact of this programme could not have been very high at the best of times. The Country Statement for India at the 1974 World Population Conference in Bucharest with its slogans "Development is the best contraceptive", is also an acknowledgement that more fundamental changes are necessary before the small family norm can be internalised. (World Population Conference, 1974). The approach document to the Fifth Five Year Plan saw FP as part of the integrated package with health and nutrition in the Minimum Needs Programme (Planning Commission. 1977). However, these pious intentions remained unredeemed and from 1975 onwards, in the holocaust of the Emergency, all voices of reason were drowned.

The year 1977 saw a change in government, a change that had taken place at least to some extent as a direct reaction to an unpopular FP programme. The new government redesignated the department as that of Family Welfare and seemed anxious not to repeat the zeal for birth control through sterilisation The Policy statement of the department of June 1977, stressed the voluntary nature of the programme, emphasised the cafeterial approach (allowing the acceptor to choose from a wide variety of methods) and recognised the need of linking FP with other welfare programmes. (GOI, 1977). However, it also expressed concern with the high population growth rate, and fixed birth rate targets of 30 and 25 per thousand to be achieved by the end of the fifth and sixth Plan periods respectively, (as against the then current 34.6. in 1973 as per Sample Registration estimates). It was also stated that the policy of linking eight percent central aid to the states to their FW performance was to continue. In a separate publication " guidelines for media and extensions personne" humility of approach and the pro-mother and pro-child nature of the programme were stressed (FWP, 1977). But the Minister for Health and F.W. made it clear in numerous press statements that incentives for sterilisation would continue. In effect, while some lifting of pressure certainly took place, no real change occured, and certainly no basic assumptions were challenged either by the Janata Party government, or by the Congress government that followed.

The Assumptions Behind The Strategy of Motivation: The 'Relevance' of Theory

We shall now examine the theoretical assumptions on which the entire motivational strategy was founded. Intellectual support for motivational attempts in the family planning programme, were imported mainly from American agricultural extensions and industrial psychology experience. Continued support was provided, once motivation did become the accepted strategy, from KAP (Knowledge, Attitude and Practice) studies in family planning and from 'communications' theory. The periodic evalutions of the programme (twice by the Planning Commission, and twice by the United Nations) also dealt with the theoretical issues.

The classical "diffusion model" that theorised on how and why innovations were adopted was an American agricultural extension creation. It demarcated the following stages in the diffusion of an invention — awareness, interest, evaluation, trial, adoption — and classified the target population into innovators early adopters, non-adopters and so on. Informal sources of information were held to be the most important at the awareness and interest stages, and neighbours and friends were named as

the most important motivators at the evaluation, trial and adoption stages. This theoretical framework was held to have usefulness for "people who are faced with the problem of diffusing new ideas and practices". (Bohlen, 1957).

Of the social and industrial psychology theories that lent support to motivational experiments in India, the following deserve mention :

(a) Maslow's theory of the Heirarchy of Needs that graded human emotional needs as "basic psychological safety, belongingness and love, esteem, and self-fulfilment needs", in that order (Maslow, 1954). Satisfaction of needs at one level motivates the individual to seek satisfaction of needs at the next level, and so on. The most important applications of Maslow's ideas, have been in the labour management and advertisement fields.

(b) McClelland's theory of Need Achievements that stated as a first premise that an individual's success in economic activities was due to his need for achievement or "N-Ach" (McClelland and Winter, 1969). Further premises, developed over several years, were that a society's levels of economic achievement depended on prevalent levels of N. - Ach and that it was possible to teach N-Ach. The last belief had important implications for the Indian FP programme, where much of the motivational strategy was based on the belief that the extension educators could teach the small family norm.

(c) Herzberg's Motivation Hygiene theory which opined that in a work situation, achievement was affected more by the workers' inner urge to succeed than by environmental factors (Herzberg, 1966). The latter had more importance as sources of dissatisfaction.

All these theories had an element of psychological determinism about them. Their view of the individual was that of a 'blank field' that would produce predetermined responses to given stimuli. Developed in the context of early and aggresive capitalist growth, they had a totally atomised concept of a human being who could be egged on through this or that process to have more "N-Ach" or more "inherent urge to succeed". Instead of viewing the individual as a product of a set of social circumstances, they viewed society as the product of differential drive/or N. Ach of its individual components. Only this totally top-sided view of history and society could produce the delusion that 'small family norm' could be taught regardless of its relevance to the life situation of a particular couple.

The other important source of intellectual support came from theories on communications research, developed orginally in the advertising and broadcasting fields, but later studied with particular reference to family planning. Communications research developed an impressive vocabulary of its own. Communication was broken up into its "main elements"- source, message, channel, receiver, bottlenecks, networks and so on. Great importance was attached to identifying particular areas of communication "breakdown" and removing the particular source of a problem. A certain amount of communications research also went into special areas of FP motivation like the whole question of incentives. Incentives were formally classified into positive/ negative, acceptor/diffusor, individual/group, immediate/delayed Rogers, a prolific writer on communications, worte regarding incentives, that while they do result in an increase in the "quantity of FP acceptance", they are likely to affect "quality" adversely. Rogers, (1973). However such cautions were seldom heeded by those on the programme bandwagon, and more encouraging findings of communications research have continued to enrich motivation vocabulary.

Once the programme was properly launched in India, KAP studies conducted by the department itself, as well as by obliging university faculties, became the main prop of the programme against which motivational strategies were planned and evaluated. Rao and Mullick have reviewed over 200 of these studies, and their main theme is that of a KAP gap in India. (Rao and Mullick, 1974). Awareness of FP methods is high, attitudes towards FP are favourable, but the actual practice of family planning by eligible couples is low. The model is obviously based on the classical diffusion theory outlined above. The methodology of the KAP studies has come under increasing attack in recent years. It is to be doubted if a simple linear relationship between K, A, and P exists in as complex an area as this. The measurement of attitudes through surveys or ordinal scales is again of questionable validity. There is, in any case, a vast difference between an attitude, which is a complex socio-psychological entity and an opinion, which is what the questionaires used in the KAP studies elicited.

Some of the inadequacies of the theoretical bases of the motivational strategy are pointed out above. Certain other and deeper fallacies however, have affected the entire programme and we can now turn to these.

The FP programme was prompted in the main by a fear of population size, that is, by (correct or incorrect) considerations of macro population policy. It being unrealistic to expect that family planning decisions should reflect population policy norms rather than individual life experiences, people were quite dishonestly sought to be converted with the message that the small family norm was good for them; proposition that was simply not correct. Considerable evidence was available even in the late sixties that a large family norm may be more suitable in certain situations (for instance in poor, labour intensive agrarian economies and where poorer classes are subject to heavy depletion in children ever born). Some of this sort of understanding did creep into the programme rhetoric from time to time, but made no real difference, as the real moving force behind the programme was never the happiness of individul families

As far as the macro understanding goes, it is not difficult to see through it at all. The argument that over population eats up the gains of developments is not a new one. Not only does it divert attention from more fundamental questions like models of development or distribution of resources; one also senses behind it a fear of people, people of certain nations, certain races and certain classes. It is another manifestation of the old Malthusian bogey that the poor are responsible for their own poverty because of their large numbers.

Birth control, which was all that family planning ever meant in India, can be advocated on many grounds. But certainly it cannot be advocated as a uniform prescription for all, without any regard for human dignity or individual liberty. The events of 1977 amply illustrated that the people would not buy an irrelevant product, however sophisticated the packaging. The tragedy is that no real lessons appear to have been learnt.

tablets. That night the wife received severe beating from the husband. He suspected that his wife had used one foam tablet with another man.

Case 2 : Having got fed up with her husband forcing her to undergo repeated abortions a woman quietly got an IUD inserted. The husband got suspicious and forced his wife to get it removed. Inspite of removing the device, she was thereafter maltreated and beaten up often. After a few months inspite of her being pregnant she was thrown out of the house in the middle of the night, the reason being that she had not taken her husband's permission to get the IUD inserted.

Case 3 : There was a case of a doctor's wife who had to undergo repeated abortions each time after a 'sex determination test' revealed a female foetus.

Case 4 : Women have to bear the burden of looking after the family and also take the responsibility of contraception. There were several instances when a woman could not be offered any method immediately as she required treatment for some gynaecological complaint. The period of treatment was always short — a month or two in each case. Her husband would be asked to use a condom or refrain himself till she was alright. But in most cases the women would conceive during this period and either continue with an unwanted pregnancy or be forced to undergo an abortion.

Any one who has worked in FP clinics has come across women belonging to various religious groups who demand oral pills to postpone their menstrual periods so that they could participate fully in religious and social functions or even go for an outing. If given a chance, women can decide how they would like to utilise scientific discoveries.

Conclusion

In conclusion, the poor women of the third world countries like India get exploited not only by the government, the research institutes, private individuals in the field of contraceptive research but also by men who care very little about their health and their comforts. Research on birth control measures which could be used by men has not been undertaken with any degree of seriousness.

For instance although the condom is really a harmless and effective method for men, no serious studies have been conducted on its being accepted or rejected by men. Women just leave condoms behind at the hospitals if they are distributed knowing fully well that husbands will not use them. The statistics on condoms are based not on the numbers used but on the total number issued. There is no proper follow-up nor any serious effort to promote this harmless contraceptive. Is it because it is to be used by men ?

A BIZARRE MEDLEY OF CARROTS

vimal balasubrahmanyan

In the last two years the government in achieving its aims of population control has proposed a number of incentives and disincentives. The author has compiled reports from newspapers in Hyderabad, which tell eloquent story about the government's priorities with regard to the family planning programme.

The following collection of news items over the period 1982-84 presents a picture of the Establishment's preoccupation over incentives and disincentives to achieve population control. They are arranged in a roughly chronological order and a number of the items happen to be from Andhra Pradesh because they were reported in newspapers in Hyderabad where I live. If the readers were to go through newspapers pulished from other cities the picture from other states would be much the same. I've left out a large number of items which tend to be repetitive and which are only too familiar today to the average newspaper reader in this country ie, announcement of a 'camp' with date and venue, total number of operations proposed to be performed and quantum of incentive money offered. I've included a few oddities which are not strictly about incentives but which add further piquancy to the total mosaic. I refrain from making any comment as the collage speaks eloquently for itself.

1982

⚙ The Bihar cabinet sub-committee on family welfare announces 33 cash prizes of Rs. 10 000 each for gram panchayats achieving the "highest target" of sterilisations in the current year. As second and third prizes 66 cash awards would be given to gram panchayats at the rate of Rs. 5,000 and Rs. 3,000 each respectively.

⚙ Extract from a panel discussion on Calcutta Doordarshan's family welfare programme One doctor comments on the uneven performance of different states in curbing the birth rate and another responds : "I suggest, but you may not like the idea, that birth control should be made compulsory by law."

⚙ A new scheme is introduced on an experimental basis by the union ministry of health to enlist the help of private practitioners to achieve tubectomy targets. A private practitioner will be entitled to receive Rs. 50 for each case of tubectomy out of the admissible compensation amount of Rs. 170 to the acceptor, irrespective of whether or not the doctor charges his own fee from the acceptor.

⚙ Industrialists led by J.R.D. Tata announce a contribution of Rs. 10 lakhs to the Family Planning Foundation of India and Rs. 5 lakhs every year hence forth. Mr. Tata tells newsmen that the allocation of Rs. 1,000 crores for FP in the Sixth plan is barely one per cent of the total outlay and is inadequate to check population growth.

⚙ Mr. Sat Pal Mittal, MP and chairman of the Indian Association of Parliamentarians on Population and Development. suggests incentives for FP acceptors like : cash awards, additional bonus, allotment of houses, plots, commercial shops or booths, rebate in income-tax and exemptions from import duty. Other suggestions : three increments for an employee opting for a terminal method after one child and two increments for an employee opting for terminal method after two children However, an employee having a third child should have his increment deferred by six months, and by one year for any subsequent birth.

⚙ Package of disincentives suggested to the health ministry by the Asian Parliamentary Forum for families with more than two children : higher rate of interest on loans, low priority in housing, higher rate of income tax. leave travel expenses only for two children; free medical treatment or reimbursement for only two children, no paid maternity leave for women after two children, public officials who exceed the limit of two children during their tenure of office be made to resign from office.

1983

⚙ Union government announces that green cards will be issued to individual acceptors of terminal methods after two children. Such green card holders will be accorded recognition, priority attention and preferential treatment.

⚙ During 1982-83, East Godavari district performed 27,937 sterilisations against the target of 27,900 thus giving 100.13% achievement for the district.

⚙ At special sterilisation camps organised in three AP towns, State Bank of India provided incentive

money at the rate of Rs. 115 per woman and Rs. 95 per man in addition to gifts for motivators.

⚙ A laparascopic 'mela' took place in Kumbakonam, the city of festivals in June 1983 when as many as 1,225 women were operated upon. The district collector who organised the camp said it was a world record for a single day. So great was the response that the camp was extended for a second day. The highlight is described as the fact that as many as 263 women were below 25.

⚙ Maharashtra having won a Rs. 2.5 crore award for outstanding FP parformance in 1982-83, announces an ambitious target of 687,000 sterilisations in 1983-84, though the target fixed for this state by the centre is only 601,000 sterilisations.

⚙ The Gujarat goverment announces a 20-day foreign trip for district panchayat officers and employees with best performance in family welfare programme. The new scheme is introduced to maintain 'round-the-year' tempo of the programme. District officials with best performance would be sent on study tours to foreign countries at state government expense while the staff of taluka and village panchayats would be sent on a 20-day tour within the country.

⚙ The Kerala government offers incentives of a would tour at government expense to the collector of the district which registers the maximum number of FP operations in a two-month campaign. During the programme incentives to acceptors would be enhanced from Rs. 145 to Rs 170 for women. Men undergoing vasectomy would get Rs. 155 while promoters would receive Rs. 20 for each vasectomy case and Rs. 15 for each tubectomy against the earlier Rs.10. The state health minister expresses the hope that Kerala would win the Rs 2.5 crore cash award given every year by the Union government to that state which performs the maximum number of sterilisations.

⚙ The Delhi Administration announces 'attractive' prizes like wrist watches and cash awards for motivators and acceptors as part of a family welfare programme.

⚙ After the announcement of an enhanced incentive of Rs. 200 for acceptors of sterilisation, there was an unprecedented turn-out at FP camps in Madras --posing problems for the organisers who ran out of funds.

⚙ A health ministry working group on incentives and disincentives suggests that any violation of the small family norm should disqualify a person from standing for an election. Such violation should also disqualify a person from appointment to university senates, directorship of a bank, vice-chancellorship and gybernatorial posts.

⚙ An expert group appointed by the Family planning Foundation of India, chaired by Justice G. D. Khosla, reiterates the disincentives recommended earlier by bodies like the Asian Parliamentary Forum and other working groups (listed in the earlier news items). In addition the Khosla committee suggests low priority for admission into educational institutions for third and subsequent children.

⚙ A DAVP ad issued by the Delhi Administration announces special attractions by lucky draw during a family welfare campaign : **Male sterilisation** : (apart from normal incentives) : Rajdoot motorcycle, TV, Phillips transistor radio, and HMT watches. **Copper T** (apart from normal incentives) : Colour TV, black and white TV, pressure cookers and HMT ladies watches. The ad urges readers to 'avail opportunity' and says : "Do not wait for tomorrow".

1984

⚙ TISCO of Jamshedpur wins the 1983 award from FICCI (Federation of Indian Chambers of Commerce and Industry) for promotion of FP among workers. TISCO's FP programme achieved 7,249 sterilisations during 1982-83.

⚙ Health ministry's advice to state governments on wooing the public to take to sterilisation : issue green cards entitling acceptors to jump the queue for certain facilities and to provide five state lottery tickets of the next draw to acceptors.

⚙ The Andhra Pradesh state government gears itself to achieve the FP target for 1984-85 through a larger number of camps and more incentive schemes. Acceptors' awards to carry prizes of Rs. 400, 200 and 100 through a lottery system in sterilisation camps where over 100 operations are conducted.

⚙ A DAVP ad for a special FP drive in Delhi announces a target of 7,000 sterilisations and 10,000 IUD insertions. To achieve this an 'additional' amount of Rs. 25 and Rs. 5 respectively would be given to the motivator for each case of sterilisation and IUD.

⚙ The Sadhana Samiti in collaboration with the AP government organises a cartoon competition with cash prizes on the theme of family welfare, the

topics being : small family, spacing, sterilisation, MTP, late marriage and maternal and child services.

⚙ The Kerala government announces a lottery exclusively for sterilisation acceptors. Men and women undergoing the operation would receive free lottery tickets and there would be a draw once every three months.

⚙ The Population Advisory Council has before it a proposal by which a public servent will be sacked if a child is born to him besides the two or more existing children after one year from the prescribed date. Other proposals : Security bond of Rs. one lakh maturing after 20 years for those undergoing sterilisation after one or two daughters; a bond of Rs. 60,000 for those undergoing sterilisation after one son and one daughter or after one or two sons; income tax rebate for persons not having more than two children; to promote late marriage employers should pay Rs. 25 per moth to unmarried working girls over 20 years with a matching contribution by the government for three years. The amount will be credited to their account and will be available after three years. To postpone the birth of the first and second child a small monthly allowance may be paid to newly married employees.

⚙ The AP health minister Rammuni Reddy, calls for a hike in incentives for FP acceptors, citing the example of Maharashtra where such a hike enabled that state to bag the cash award of Rs. 2.5 crores. He feels that if the state fixes a target of five lakh sterilisations, the extra expenditure involved would be offset by the bagging of the national cash award.

⚙ The Madhya Pradesh government introduces a 'green card' system for those undergoing sterilisation after two children : each green card holder will get preference in employment, health cover and financial assistance under various schemes; two years relaxation in age for employment and 5% extra marks in interviews; also free medicine and medical care in government hospitals; children need not pay fees in professional courses. In rural areas, landless card holders will get priority in land allotment and house plots, as well as 20 bamboos and ten wooden poles free of cost from the nearest forest depot, licences to open retail shops for fuel and kerosene, priority in allotment of cement, priority in getting loans for milk cattle, grants for setting up wells, pumps and bio-gas plants.

⚙ The *Indian Express* reports a 'massive fraud' and "statistisal acrobatics" in Copper T figures by the Maharashtra government in its efforts to ensure that it again wins the Rs. 2.5 crore annual cash prize awarded by the Union government.

⚙ The Rotary Club announces a two-day 'mini' camp at Nellore in AP with a target of 300 sterilisations. An incentive of Rs. 145 for women and Rs. 125 for men will be given, plus free food to attendants and milk to children accompanying the parents.

⚙ The Punjab health secretary announces a plan to introduce a raffle scheme to attract acceptors of sterilisation. Apart from prize Rs. 1,000 each at monthly draws, a quarterly state-level draw would have a first prize of Rs. one lakh. The scheme would not be a burden on the exchequer as the funds would be drawn from the prize money earlier won by the state from the centre for its FP performance. Approval from the centre is awaited.

THEORIES OF REPRODUCTIVE BEHAVIOR

A Marxist Critique

martha e gimenez

This article is reproduced from the Review of Radical Political Economics, Micro-economic theories that view children as consumer goods or home produced goods which parents either purchase or produce subject to income, price, and taste constraints, are essentially voluntaristic. Sociological theories, on the other hand, stress the socially determined and coercive nature of reproductive behavior. From the standpoint of historical materialism, both theories are open to criticism. It is argued that a scientific analysis of reproduction should transcend the voluntaristic and deterministic alernatives which are the hallmark of bourgeois thought. Instead, using the method of historical materialism, reproduction should be conceptualized in structural, concrete, and historical terms; i.e., as the reflection of the reproductive strategies of classes in the context of a given mode of production This article is reproduced from the Review of Radical Political Economics.

Economics is all about how people make choices. Sociology is all about why they don't have any choices to make. Historical Materialism is all about how and why people make historically specific choices.[2]

Current theories of fertility fall within voluntaristic or deterministic frameworks. Microeconomic theories are voluntaristic: they rest on the assumption that individuals are free to decide whether they want to have children and how many, and that such decisions are based upon a comparsion between the utilities to be expected from children and those expected from allocating resources to other goods.[3] Sociological theories, on the other hand, are deterministic. Sociologically, reproductive behavior[4] is socially determined; it is rooted in the social and economic structure which determine the set of role alternatives, rewards, and punishments confronting individuals at a given time and, consequently, it cannot be adequately investigated if viewed in purely voluntaristic terms.[5]

The shortcomings of microeconomic and sociological theories of reproductive behavior may be traced to their ahistorical approach to the study of social reality and their conceptualization of reproduction in terms of individual behavior and its determinants. Historical materialism[6] transcends the opposition between voluntaristic and deterministic viewpoints and offers a historical and structural approach to the study of reproduction which shifts the focus of theoretical concern to the reproductive strategies of classes and sectors of classes in historically specific contexts.

The epigraph above sums up the content of this essay. The methodological assumptions underlying microeconomic and sociological theories will be outlined and critically examined. Rather than exploring specific applications of these theories, I develop a critique of their theoretical foundations which is based on my interpretation of historical materialism. Several conditions for a scientific Marxist analysis of fertility are delineated.

The Economic Theory of Fertility

The dominant contemporary theoretical efforts at explaining fertility behavior stem from the use of microeconomic theory. Children are viewed as consumer durables[7] or, in the most recent developments, as household produced goods[8]. The main assumptions common to both types of analyses is that households (like firms) behave rationally, maximizing their utility in a context of scarcity: households characterized by given tastes or preferences can choose to consume/produce children and/or commodities. The theory of fertility as consumer behavior also emphasizes income and price constraints: households with given tastes"... are viewed as maximizing utility subject to the constraints of income and prices Thus three factors—income, tastes, and prices—are the basic building blocks of fertility behavior.[9] The theory of fertility as productive behavior adds a fourth relevant constraint: time. The quantity and quality of children and other household goods will be thus a function of the time and resources allocated to their production.

The essence of this approach to fertility behavior lies in the importance given to choice. It is assumed that children and commodities can be described by an indifference curve whose points represent combinations of children and commodities providing the same amount of utility to the household. Households are, consequently, indifferent when confronting the

options offered by an indifference curve and, when facing a set of indifference curves they will choose that which — given their income and price limitations — maximizes their utility.

The Sociological Criticism

Sociologists emphasize social constraints on individual choice. Sociologically, reproductive behavior is socially constrained behavior; it is a key dimension of adult sex roles and, as such, it is supported by a network of social, economic, and psychological rewards and punishments that rule out the desirability of alternatives to the performance of family roles.[10]

Sociologists have convincingly argued that children cannot be appropriately considered as equivalent to consumer goods or home produced goods because the social context of reproduction introduces elements in their process of "consumption/production" that render untenable the main assumptions upon which the economic model rests. Essentially, this means that parents are not free to choose the quality and quantity of children. With respect to quantity, societies vary in their normatively sanctioned desired family size; advanced Western societies seem to have settled upon two as the minimum. Quantity interacts with quality as it is assumed that an only child is likely to have "problems" that could be avoided by having at least two.[11] With respect to quality, parents cannot raise their children at a level separate from their own or that of other siblings; i.e., they are not free to choose between possible combinations of high and low quality children.

Furthermore, parents cannot raise children according to arbitrary rules : there are general socially established minimum standards of child quality as well as specific standards linked to class, socioeconomic status, ethnicity, religion, culture, etc. Finally, parents lack control over the initial quality of their children so that they lack a basis for balancing their potential utility with that of other goods; they cannot reject them if they do not conform to expectations nor can they exchange them or abuse them as they could any other good at their disposal.[12]

The substance of the sociological approach to productive behavior is the following:

> People make their "voluntary" reproductive choices in an institutional context that severely constrains them not to choose non-marriage, not to choose childlessness, not to choose only one child, and even not to limit themselves solely to two children.[13]

Like economists, sociologists begin "post festum" with the results of the process of historical development (e.g., norms, sex roles. desired family size, parental roles, etc.) having acquired the stability of coercive and constraining "social facts." Neither economists nor sociologists deal with the historical specificity of the fetished facts they study and this is why, from the standpoint of historical materialism, their scientific contributions are inherently ideological.

The Marxist Critique

The ideological nature of economic and sociological theories does not stem from deliberate distortions nor from errors that could be eventually corrected. Under capitalist conditions, ideology becomes an inextricable aspect of the social sciences to the extent that those sciences are limited to the partial investigation of social reality thus overlooking aspects of it which while less obvious and apparent are just as important and as real. The material basis of this phenomenon is rooted in the peculiar nature of the social reality treated by capitalist production whose defining feature is the "fetishism of commodities '.[14]

Capitalism, as a mode of production presuppose the universalization of commodity production; i.e. the transformation of labour-power into a commodity and the satisfaction of all needs through market exchanges. It presupposes, therefore, the existence of two classes; the capitalist class which owns the means of production and the working class which owns nothing but its labor-power and must sell it in the market for wages which it must subsequently exchange for goods and services needed for survival. The reality of the market is only one aspect of the totality of capitalist relations. This is the sphere of exchange and circulation of commodities which Marx describes as follows:

> . . . (it) is ... a very Eden of the innate rights of man. There alone rule Freedom, Equality, Property, and Bentham, because both buyer and seller of a commodity, say of labor-power, are constrained only by their own free will . . . Equality because each enters into relation with the other as with a simple owner of commodities, and they exchange equivalent for equivalent. Property, because each disposes only of what is his own. And Bentham, because each looks only to himself. The only force that brings them together and puts them in relation with each other, is the selfishness, the gain, and the private interests of each.[15]

At the level of production there is neither freedom nor equality. Property relations assert themselves as

relations of domination : workers are actually ' free" to choose between starving or working under the sway of capital and the contradiction between their interests and those of the capitalist class results in protracted class struggles whose outcome determine the working conditions found at a given time.

In the capitalist mode of production, the market mystifies the appropriation of unpaid surplus-value by the capitalist class because, at the level of market exchange it appears as if capitalists and workers exchanged equivalent for equivalent; as if the wage were equivalent to the workers' output. Actually, the value of wages is equivalent only to the value of the goods and services needed to reproduce the labor force on a daily and generational basis.[16] The value of the workers' total output, on the other hand, is greater than the value of wages in a proportion determined, ultimately, by the class struggle; the difference is surplus-value, the product of surplus labor time, which capitalists appropriate at the level of production and realize at the level of market exchange.

The market exchange of commodities, through the tyranny of the laws of supply and demand, obscures not only the relations of production between capitalists and workers but also the relations among capitalists themselves which, in their eyes appear as relations among things — their products — which they are unable to control. This is the fetishism of commodities which results in the perception of things and relations among things while class relations and relations of production remain outside the purview of the members of capitalist societies, including social scientists.

The universalization of commodity production ensures the pervasiveness of commodity fetishism which is, from the standpoint of historical materialism, the material basis for determining the boundaries between science and ideology[17] as well as their inextricable combination to the extent that scientific practice remains limited to investigating the level of exchange and circulation of commodities while overlooking the level of production. Marx states the point as follows:

> Man's reflections on the forms of social life and, consequently, also his scientific analysis of those forms, take a course directly opposite to that of their actual historical development. He begins, post festum, with the results of the process of development ready to hand before him. The characters that stamp products as commodities, and whose establishment is a necessary preliminary to the circulation of commodities, have already acquired the stability of natural, self-understood forms of social life, before man seeks to decipher, not their historical character, for in his eyes they are immutable, but their meaning.. The categories of bourgeois economy consists of such like forms. They are forms of thought expressing with social validity the conditions and relations of a definite, historically determined mode of production.[18]

The economic theory of fertility is an object lesson on the meaning of commodity fetishism and, as such, it shares the basic ideological flaws of economic theory in particular and social science in general criticized by Godelier.[19] An application of Godelier's major critical insights to current theorizing about fertility can be summarized in four major points.

1. The microeconomic approach to fertility takes as a point of departure the obvious and visible maximizing behavior of individuals and overlooks the structures that render possible such forms of individual reproductive behavior. It bypasses structures which are "... part of reality but not of visible relationships"[20] and limits the scientific analysis of fertility to its fetishized dimensions. It does not inquire, in other words, into the historically specific conditions under which it becomes possible for scientists to conceptualize fertility behavior in those terms and for people to ask themselves whether they can "afford" a child; instead, it justifies its analysis on the basis of a formal theory of rational choice.[21]

2. It defines fertility behavior in terms of a formal theory of rational action as optimizing behavior in a context of scarcity. Such a formal theory of rationality is a poor basis for a scientific analysis of reproductive behavior because it explains nothing about its content, its origin, and its change. The use of formal rationality is ideological. Whether it is conceived as a universal feature of human nature or as a product of capitalist development, formal rationality functions as an apologia of capitalism. In its light capitalism can be pseudo-deduced from human nature (and consequently endowed with ahistorical immutability) or it can be considered as the source of rationality thus relegating everything else to the realm of tradition, religion, custom, and other substitutes for reasoned analysis.[22]

3. The reliance on formal rationality and individual behavior necessarily leads to neglect of the social nature of the criteria by which individuals

maximize their utility. The subjective utility of children for individuals or households is taken as the basis for explaining how reproductive behavior operates. It is assumed that those utilities, as well as their hierarchical ordering in a map of indifference curves responds solely to individual subjective preferences which can be collected and statistically analyzed, thus providing a pseudoscientific analysis of social needs. It is obvious that such statistical analyses are insufficient to scientifically explain not only the needs and hierarchy of needs dominant in a given social formation at a given time but also, what is more important, the reason why the satisfaction of some needs as well as the form in which such needs are satisfied are deemed more "rational" than others.

4. The theory of choice is based upon a conceptualization of income as an individual attribute. Income is viewed in purely quantitative terms : the amount of income accruing to individuals thus determines, given tastes and market prices, the combination of goods and children that best maximizes their utility. The exclusive concern with the quantity of income reflects the narrow basis of the analysis which remains at the level of market relations and unavoidably overlooks the relevance, for the explanation of fertility behavior, of the relations of production and class relations in which all individuals participate. It obscures the existence of qualitative differences in the sources of individuals' income, differences that stem from their specific location in the mode of production.

The scientific kernel of the economic theory of fertility lies in the identification of the economic constraints that shape fertility behavior under capitalist conditions, and the articulation of those constraints with individuals' tastes into a theory potentially useful for the study of reproductive behavior. The universalization of commodity production, which implies the satisfaction of all needs through the market, does incorporate child-bearing and rearing into market relations both symbolically and practically to the extent that such activities presuppose monetary outlays. Market considerations and relations do invade the household forcing its individual members to behave in an optimizing manner in order to maintain or improve their standard of living and that optimizing behavior necessarily affects reproduction.

On the other hand, the economists' insights on the nature of fertility behavior are scientific for they express "...with social validity the conditions and relations of a definite historically determined mode of production;"[23] but they are also ideological because they do not acknowledge the historical nature of those conditions: i.e., their basis on the capitalist mode of production which not only makes possible the theory and the practice of fertility behavior as consumer/producer behavior but also gives it a historically specific content. Their analysis is limited to the subjective. individual, and formal aspects of fertility behavior; i.e. to its fetishized form.

The Marxist Alternative

These critcisms suggest three specific conditions for a scientific Marxist analysis of reproductive decisions.

1. It should define reproduction in structural rather than individual terms.

Instead of investigating reproductive behavior primarily as the behavior of individuals who, given certain individual attributes (income and tastes) and market prices, choose to consume/produce children, Marxist analysis would investigate the reproductive structures characterizing a given social formation at a given time. As Engels pointed out,

> ... according to the materialistic conception, the determining factor in history is, in the final instance, the production and reproduction of immediate life. This, again, is of a twofold character : on the one side, the production of the means of existence ... on the other side, the production of human beings themselves, the propagation of the species.[24]

Under capitalist conditions, given the twofold nature of production, it becomes necessary to investigate the relationship between the capitalist mode of production and the capitalist mode of reproduction (in the biological and social sense) it presupposes. The capitalist mode of reproduction is the complex structured totality formed by the combination of the material and social elements that enter into the biological and social reproduction of human beings through historically specific (i.e., capitalist) relations of reproduction (relations between the sexes, independent from their will, mediated through their relationship to the material and social conditions of production and reproduction) [25] Consequently, the study of the relationship between capitalist modes of production and reproduction is not equivalent to studying the "interaction" between "family" and the "economy". At the market level, economy and family appear as things in themselves that "interact" with each other in ways that reproduce market relations thus obscuring the relations of production

and the relations of reproduction which underlie market behavior. Under capitalist conditions (as well as in all modes of production based on the private ownership of the means of production) the social relations of reproduction are sexist relations. A structural and historical analysis of the relationship between the capitalist modes of production and reproduction entails, therefore, the investigation of the relationship between capitalist contradictions and sexism both at the levels of public production and at the level of the modes of reproduction that characterize specific classes and sectors of classes. From the standpoint of historical materialism, this investigation is a nececssary preliminary step for the sound study of reproductive patterns for it would disclose the historically specific constraints determining individual reproductive behavior at the market level.

2. It should define reproduction in real, concrete terms, rather than formal terms.[26]

In the *Grundrisse,* in the section on "The Method of Political Economy,"[27] Marx makes an important distinction between three kinds of concepts : imaginary concretes, abstractions of simple definitions, and concrete concepts. The substance of his argument is the following:

It seems correct to begin with the real and the concrete, with the real precondition, thus to begin, in Economics, with e.g , the population, which is the foundation and the subject of the entire social act of production. However, on closer examination this proves false. The population is an abstraction if I leave out, for example, the classes of which it is composed. These classes in turn are an empty phrase if I am not familiar with the elements on which they rest ..... If I were to begin with the population, this would be a chaotic conception (Vorstellung) of the whole, and would then by means of further determination, move analytically towards ever more simple concepts (bhegriff), from the imagined concrete towards ever thinner abstractions until I have arrived at the simplest determinations. From there the journey would have to be retraced until I had finally arrived at population again but this time not as the chaotic conception of the whole, but as a rich totality of many determinations and relations. The concrete is concrete because it is the concentration of many determinations, hence the unity of the diverse.[28]

The economic theory of fertility is a "thin abstraction" a formal analytical construct that distills the essence of the reproductive experience of the vast majority of the people living under capitalist conditions and reifies it into an ahistorical, formal theory of rational choice. The development of a real and concrete concept of reproduction as a "totality of many determinations and relations" involves "retracing the journey" in order to elucidate its historically specific structural foundations. This calls for the investigation of the content given to formally rational individual behavior by the location of individuals and households in the mode of production. In the context of capitalist social formations, the apparently homogeneous population of individuals who, at the market level of analysis appear engaged in formally similar optimizing behavior as consumers/producers of children, disappears at the level of production where it is replaced by a heterogeneous population divided in classes whose rational behavior has qualitatively different contents.

At the level of production, the rational behavior of the capitalist class is dominated by the problem of investments; how to invest to maximize profits. The rationality of the working class, on the other hand, is dominated by the problem of survival : to sell labor-power for the highest possible wages. Survival is ensured by compliance with the goals of the capitalist class and, in that sense, the rationality of the working class is " ... complementary, derivative, and dependent" upon the rationality of the capitalist class.[29]

The relationship between these classes is contradictory and complementary at the same time. The contradiction between capital and labor is obvious : the higher the wages, the lower the profits and vice versa; hence the presence of class struggles as a permanent feature of capitalism. They are complementary in terms of their role in the production process : the ongoing smooth functioning of capitalism depends both on the rational behavior of the capitalist class (e.g , making adequate investment decisions, and the rational behavior of the working class (e.g , adapting its needs and work patterns of the conditions set by the capitalist organization of production). The rational behavior of the capitalist class can be fully effective to the extent it counts with a subordinate, malleable, and controllable labor force It follows that, while the rationality of the capitalist class is unitary (i.e., its class interests and its goals as defined in the production process coincide), the rationality of the working class has contradictory dimensions rooted in the context from which it is defined. From the standpoint of the working class, the rational pursuit of its class interests is in the contradiction with capitalist interests both in the short (e.g., struggle for higher

wages/salaries) and the long run (e.g., struggle to abolish capitalism). On the other hand, from the standpoint of the capitalist class, the working class behaves rationally to the extent it overlooks its own interests and, instead, conforms and adapts its behavior to capitalist demands inside and outside the production process.

At the level of reproduction, it becomes necessary to investigate the ways in which capitalist and working class rationality (i.e., the pursuit of their class interests) affect the reproductive behavior of both classes. To define reproduction in real, concrete terms means, therefore, to inquire into the conditions surrounding the reproduction of classes rather than merely the reproduction of "individuals" or the "human species."

With respect to the reproduction of the rational pursuit of class interest, rational profit-seeking behavior and reproductive patterns are, in principle, functionally related. Reproduction is an integral part of the overall rational behavior of the capitalist class aimed at preserving its economic and political power. Capitalist class families seek to ensure that their children will also be members of the capitalist class and this inevitably affects their family-size decisions.

The analysis of the reproductive patterns of the working class is more complex because the rational pursuit of class interest and the content of formally rational reproductive behavior are relatively independent. Workers cannot directly affect the outcome of the class struggle nor further their class interests through changes in their reproductive patterns. This assessment of the relationship between reproduction and working-class interests rests upon the crucial distinction between *labour-power*, the capacity for physical and intellectual activity, and *laborers* or workers, the owners of labor-power. While the production of labor-power presupposes the existence and reproduction of the workers, the demand for labor and the level of wages are determined not by the existent number of workers, but by economic and political considerations establishing the quantity and quality of labor-power needed at a given time. Under capitalist conditions, whatever their rate of natural increase might be, workers are constantly in excess of the demand for labor-power. Reproductive decisions in other words, do not affect, directly, the size of the reserve army of labor.

Workers do, however, respond to the uncertainties of the labor market by attempting to improve their own individual situation and this has important implications for their reproductive behavior. They may attempt to improve their children's "life chances" in the market by restricting their family size so that each child has larger claim on the family's scarce resources. On the other hand, they may find that a large family is beneficial because it increases the size of a family network which affords protection against the insecurities of the labor market. The specific ways in which different sectors of the working class adapt to changing demands for labor power and the relationship between those adaptive patterns and changes in the status of women in the context of unchanging sexist relations of reproduction are, consequently, of key importance for understanding their reproductive behavior. Rational working-class reproductive behavior is, therefore, another maniestation of the dependent, complementary, derivative rationality that suits the needs of the capitalist class. What appears at the level of the market as the rational optimizing behavior of individuals is a structural effect of the processes through which different sectors of the working class adapt their behavior to the productive and reproductive demands of the capitalist class. The changing content of that formally rational reproductive behavior reflects those changing demands and this topic will be considered in the section that follows.

3. It should analyze "taste" on an objective rather than subjective basis.

It is important to investigate the relationship between the requirements of the capitalist mode of production and the historically specific hierarchy of socially structured alternative and needs confronting different classes at a given time. Marx's analysis of the needs of the working class is pertinent at this point and applicable to all classes :

> .. the number and extent of . . . necessary wants, as also the modes of satisfying them, are themselves the products of historical development, and depend, therefore to a great extent on the degree of civilization of a country, more particularly on the conditions under which, and consequently on the habits and degree of comfort in which, the class of free laborers has been formed. In contradistinction therefore to the case of other commodities, there enters into the determination of the value of labor-power a historical and moral element.[30]

A given number of children can thus be viewed as an integral part of the "historical and moral elements" that enter in the determination of the value of labor-power which includes the means of

subsistence necessary for the reproduction of the labor-power of the workers and their future substitutes : their children.[31] Different kinds of labor-power have different values and are reproduced in contexts requiring a variable number of children. This is a matter that can be empirically determined for different classes and sectors of classes. While that number is subject to a variety of historically specific social constraints (e.g., pronatalist sex roles, norms about family size, tax advantages for families, etc.) and fluctuates in tune to changes in wage levels and market prices, there is at any given time a family size which appears rational within a framework defined by the power of the capitalist class. The extent to which that family size is overtly or tacitly used by social scientists to evaluate the rationality of the fertility behavior characterizing specific countries and/or sectors within a given country is a matter to be empirically established.

In so far as economic theories of fertility overlook the three conditions discussed above, they will retain ideological and apologetic implications for they will conceptualize capitalist reproductive behavior either ahistorically (i.e., as rooted in an utilitarian "human nature") or as the abstract result of "modernization" and "rationalization" processes. The concrete consequences of such approaches are : a) the misunderstanding of reproductive behavior and its determinants; b) the tacit acceptance of capitalist structures, processes, and contradictions which remain outside the scope of scientific concern; and c) the use of the empirical effects of capitalism as a variety of "factors" (e.g., cultural, technological, educational, etc.) that could "explain" variations in reproductive behavior.

Conclusion

As Marx pointed out in this famous passage :

> Men make their own history, but they do not make it just as they please; they do not make it under circumstances chosen by themselves, but under circumstances directly encountered, given, and transmitted from the past.[32]

The deterministic and voluntaristic theoretical assumptions underlying sociology and economics respectively are transcended by historical materialism which, while allowing for the importance of individuals active intervention in social life, it also acknowledges the historical boundaries that give meaning to that intervention and make it possible. From the standpoint of historical materialism it is as abstract and one-sided to argue that individuals are free to choose their family size given income and price limitations as it is to argue that they have no choice whatsoever because their behavior is socially determined. The economists' individualistic/utilitarian assumptions are as misleading as a basis for developing a scientific analysis of reproduction as the sociologists' oversocialized conception of man. Both capture partial or fetishized aspects of social behavior without dealing at the same time with the structures that produce and reproduce those "social facts" on an ever expanding scale. A scientific analysis of fertility cannot be limited to mapping the reified consciousness emergent in the context or universalized commodity production nor to describing the various forms in which coercive "social facts", impinge upon reproductive behavior. A scientific analysis must specify the structural mechanisms that make possible those forms of objectivity and consciousness at a given time. The identification of those mechanisms rests upon a structural concrete, and objective definition of reproduction as the reproduction of classses and relations of production in the context of a historically specific mode of production.

4. The concept of reproduction can be used to indicate three different levels of analysis : human reproduction, reproduction of the labor force, and social reproduction (Edholm, et, at. 1977). This essay has methodological critique of the economic and sociological approaches to the study of human reproduction. By theories of reproduction it is meant, consequently, theories of fertility and reproductive behavior will be used as interchangable terms. On the other hand, the critique suggests that human reproduction cannot be adequately studied in isolation from social reproduction and the reproduction of the agents of production. Such shifts in levels of analysis will be made explicit in the text and should not pose difficulties for the reader.

21. Economic rationality is equivalent to formally defined rational behavior (i.e. optimizing behavior or selection of means and ends in terms of marginal utility) and, as such, it can be understood in terms of the formal theory of rational choice which underlies much of the theoretical development of modern social science, including economics. For a detalied analysis of this point see M Godelier, *Rationality and Irrationality in Economics* (New York: Monthly Review Press. 1972) and Anthony Heath. *Rational Choice and Social Exchange*, a Critique of Exchange Theory (New York: Cambridge University Press. 1976).

25 The methodological argument developed in this essay presupposes knowledge of concepts such as mode of production, social formations, relations of p oduction mode of reproduction, relations of reproductions, and so on. It is true that the theoretical elaboration of historically specific modes of reproduction (biological and social) is still in its early stages and widespread knowledge. let alone agreement, about their adequacy cannot be expected. On the other hand, a detailed presentation of my own understanding of these issues, which I have stated in a recent article (see M. E. Gimenez, " Structuralist Marxism on 'The Woman Question,' " *Science & Society*, Fall, 1978, pp. 301-323), would necessarily break the continuity of the argument. I think, though, that readers familiar with Marxist and feminist theories should have no difficulties in understanding my usage of the concepts mode of reproduction and relation of reproduction.

26. Marx's distinction between imaginary concrete, formal, and concrete or real concepts is one of his most important, albeit cryptically stated methodological insights. The significance of these distinctions is the following : unlike empiricist and idealist epistemologics which seek an understanding of social reality through the discovery of universally valid categories of analysis, Marx's methodology shows that such categories are themselves the product of specific historical relations ; they are valid in all modes of production but on the other hand, they possess their "full validity" only for and within the historic relations that produced them (K. Marx, *Grundrise* London: Penguin, 1973), p, 105.

Rural Energy Situation : Consequences for Women's Health - A Comment

Shobha Rao

In recent years there has been a growing awareness among nutritionists and other scientists regarding the problem of undernutrition in our country. Despite the fact that several studies reported in literature come out with diverging opinions and findings, their importance cannot be overlooked since they are likely to influence national nutritional planning. One of the recent studies by Batliwala (SHR I, 2) is of interest in this context and needs to be critically studied.

The scrutiny is of importance for two reasons. First, while many studies deal with the problem of undernutrition in general, very few have discussed its nature in the case of women. Secondly, the study claims to offer an alternative facet of improving women's nutrition and health which is rather interesting and might have consequences for policy implications.

The main conclusions of the study are given as (i) women contribute the greatest share in human energy expended, but in comparison to this energy output, women get a lower share of food intake and face a nutritional deficit. (ii) In addition to nutritional deficit, women face health hazards due to the village energy system (iii) Redusing energy expenditure..... energy saving-is recommended as an additional facet of improving women's nutrition and health.

Let us start with the central issue i.e. women contribute the greatest in human energy expended. The relevant figures are given in Table 2 (1:2,). tI should be noted that not only the difference in energy expenditure of men and women is negligible, but the way these estimates are obtained is also questionable. For example, one of the assumptions is that the ratio of caloric costs for any activity for female to that for male is equal to the ratio of female BMR. The author appears to be unaware of the fact that in recent years the notion that the BMR in an individual is constant, has been questioned and evidence is coming up to show that it is not. Therefore, although we doubt very much that this could be so, it would have been better if the author had cited appropriate references. The reason why the author suspects this negligible difference is due to the fact that men on average work for 4 hours a day, whereas women work for 6 hours. However, it cannot be neglected that men are engaged in heavy activities whereas most of the activities of women are of a sedentary and moderate nature. Considering that the caloric costs of moderate and heavy activities differ significantly, the observation that the difference in energy expenditure is marginal could be well so. In short, the methodology of obtaining the estimate of energy expenditure appears to have a weak basis.

Coming to her estimate of the intake of men, women and children, the situation is even worse. She uses crude ratios such as 2:1.5:1 (balls) based on responses to oral questions put to the local women and applies this ratio to the overall cereal consumption of the family for the day thus obtainingi ntake estimates. The author gives no information whatsoever on whether this ratio is based on the responses of a sufficiently large sample of women, nor on how the figure 4.24 kg of overall cereal consumption has been arrived at. The conclusion therefore that a man has an intake surplus of 800 calories whereas a woman has an intake deficit of about 100 calcries is unacceptable in the light of the weakness of her methodology.

Further, she goes on to claim that this 'calorie gap' suffered by women is not of equal concern to all and brings in Sukhatme's theory. Her criticism of Sukhatme's theory only reveals that she is missing the essence of this theory. It is necessary to understand that it is the nutrition science itself that offers body weight and level of activity as indicators while defining calorie requirements. Thus, according to the current concepts, individuals similar in age-sex, body size, doing similar activities are assumed to have the same energy needs. Alternatively, if an indiviqual maintains his body weight and activity over time, his requirement is assumed to be constant.

Sukhatme is bringing out the fact that these assumptions are not supported by experimental data. For, if the above assumptions were true, we would not witness the large variation in intake (coefficient of variation of the order of 16 percent) of individuals similar in age-sex weight and doing similar activities (Widdowson 1962, Harris 1962). Nor would we observe the coefficient of variation in weekly mean

intakes of the same individual to be as high as 13 to 15 percent. Sukhatme thus brings out the fact that the current definition fails to explain the large variation observed in intake or balance.

His theory on the other hand explains the nature of this variation with the help of the concept of intra-individual variation. Just as the blood glucose concentration in a healthy active man in fasting condition varies between 60 mg and 120 mg per 100 ml of blood, there is evidence to show that a man can do a given amount of work on a range of intakes. Thus, intra-individual variation is the fundamental source of variation and therefore it is hard to obtain a one-to-one relationship in daily intakes and expenditure. Finally, it is worth mentioning here that intra-individual variation is related to short-term fluctuations such as observed over few weeks or months, but cannot be taken when considering long term periods (of several years or a life long period) as the author seems to consider. It would in fact be wrong to visualise this hypothesis in such a way and comment on long term adaptations and so on. Nutrition science has yet to go a long way to study the phenomenon of 'adaptation' which the author is speaking about.

The author seems to assume that undernutrition is the sole cause for the several facts mentioned such as more female deaths, high maternal mortality rates, low birth weight and so on. It is well known that a number of social and environmental factors also contribute to this and it is difficult to show a causal relationship between undernutrition and these facts. Just the same way, it has been shown that although low birth weight could be one of the factors responsible for high infant mortalityr ate, most infant deaths in developing countries are due to past neonatal causes and diarrhoea is observed to be one of the main causes, thus indicating the influence of poor environment.

Although her concern about women's health is well understood, isn't it a fact that the issue has its roots in the law status of women, both social and economical in our society. There is therefore, no dispute that every effort should be made for proper implementation of current health services to ensure that they reach needy women.

To summarise, the lack of sound methodology in obtaining estimates of intake and expenditure seriously questions the finding that women face greater nutritional deficit. Therefore, her suggestion for reducing energy expenditure or for energy saving are not appealing. Further, there is no reason to consider that physiological responses of the body for increased intake or reduced expenditure could be same. Today in developed countries individuals find ways to spend there energy by means of jogging, bicycling etc. in order to keep their muscles active and to maintain proper body stature. Therefore it is necessary to give a thought for the possible consequences, good or bad, of energy saving.

Finally, it is clear that energy saving in practice will not be achieved without enough technological and economic resources. This is not to deny the role of technology, but at the same time it is important that changes introduced for saving women's energy should fit in the culture of our rural life. For example, replacing traditional chulas by gas stoves to reduce health hazards may not be a wise step. But instead it is necessary to convince villagers that there should be a proper outlet for the smoke to go out and see that every house in fact, has one such outlet. It is our experience that in the past few years, bore-wells have been installed in almost every village but the fact is that women still go for fetching water to the old village well, without realising that that this water is unsafe for drinking. It is therefore a basic minimum education for the women for their own wellbeing that should precede such technological and other advances.

Witch Hunting Among The Bhil Meenas of Rajasthan

Narendra Gupta

The problem of witch hunting as reported by Kashtakari Sanghtana SHRI (1:2, 1984) is prevalent among all adivasi and primitive societies in varying forms. The problem as envisaged in the report has no ready solution because the tradition is very old and deeply rooted within the culture. The practice of witchcraft evolved as a system of beliefs to face the unknown supernatural world and its adverse

manifestations in day-to-day life. To find any resolution of this problem would require a greater insight into adivasi culture, environment, social and religious institutions.

Southern Rajasthan where we work, is mostly inhabitated by Bhil Meena adivasis. Here the incidence of witch-hunting has decreased considerably in the past few decades. It is now present in a different and milder form. Among the Bhil Meenas, witchcraft forms a part of magical rites and can be performed by magicians who are called as "Zangars" in the local dialect. These zangars are not medicinemen and they are approached when all other measures of resolving the crisis have failed. The first agency in any sort of crisis is the bhopa who is a faith-healer, an adivasi with powers to call supernatural spirits into his body. At a sanctified place he goes into a trance when the spirit enters him. The problem is explained to this spirit and it suggests remedies. If all such remedies fail then the possibility of a witch is considered. A magician is approached to ascertain the involvement of a witch. (There are very few magicians in this area.) These magicians by performing magical rites through the night will confirm the presence of a witch and provide either the description of witch or her exact name or address. Through another set of magical rites the magician will invoke the witch and ask about her presence in in the family facing crisis and what she requires to leave the diseased person or the family. She is never however offered any of the things she wants but tortured and forced to leave by magical charms. In some cases the woman who is believed to be a witch is brought to the magician and put in his control. There have been some instances when a woman identified as a witch was killed but not in an open trial. These women were killed secretly by the family members facing crisis. Generally witches are considered to be females in this area however there are also male witches. They are thought to be stronger than women witches.

Who is this witch? Why did such a concept and practice evolve? Some of the explorations and causes mentioned in the report in SHR seem logical but only in the present-day context. However, we need more definitive knowledge. Adivasis are a brave and courageous people. At the same time they have a carefree attitude towards life and believe in enjoying it. Therefore, poverty has a very marginal effect on them. It is only recently that they have turned agrarian and have started taking up jobs out side their homeland. The concept of storing things for the future is also very new to them. Hence any sort of condition leading to material hardship, lowered resistance to disease cannot be a sufficient reason for the continuing practice of witch hunting, which has become institutionalised in this society for centuries. Similarly, inaccessibility to health care facilities, disruption of communications and shortage of money are very new occurrencs which are not even well perceived by adivasis and cannot be the cause of frustation leading to witch hunting,

To the Bhil Meena adivasis, death is an integral part of life and is not seen as something ghastly. Death even in action (hunting, war, orb of snake bite) does not inspire awe or horror. It is also believed among them that the soul, the divine force in the living body, after death goes to the land of dead to rest with ancestors who are believed to have influenced their every day affairs, when alive. According to them this soul may also take the form of an evil spirit and return to this earth to finish its unsatisfied desires. This evil spirit on earth makes its home in the body of a human being, (mostly woman) as it is the woman who can beget. Such a woman will change into a witch. There are lots of descriptions of witches which vary from place to place.

One more possible reason for the practice of witch hunting among adivasis could be their cultural configuration which is close to nature and the core of their own cult practices. Although primitive, it is representative of their beliefs and religion. During the course of their day-to-day life they have to encounter the wildness of this configuration. Wildness provokes wildness, and it is this animistic behaviour of adivasis which finds its expression in the form of witch hunting. The reason for diminished incidence of witch hunting in this area can also be attributed to the influence on adivasis of Hindu religion. Adivasis in this area have made many adjustments to fit in with this new influence and it is always considered superior. This constant interaction with new patterns of culture has resulted in a diversity of cultural practices and traits which are less animistic.

A practice like this is barbarous and should stop, but the people who practice it, do it within a set of concepts and unless these concepts are changed, it is very difficult for people to get away from it.

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved.

Each issue of the journal will focus on one theme, but it will also carry (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

Our forthcoming issues will focus on : Health and Imperialism, People in Health Care, Systems of Medicine and Mental Health.

If you wish to write on any of these issues do let us know immediately. We have to work three months ahead of the date of publication which means that the issue on Health and Imperialism is already being worked on. A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing style of reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. These need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be nealty typed in double spacing, on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions **in a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are working on issues of interest to you.

WORKING EDITORS

Please send me Socialist Health Review for one year (four issues). I am sending Rs._____ as subscription and/or donation by Demand Draft/Cheque. (D.D. and cheque in favour of Socialist Health Review and for cheque, add Rs. 5, if outside Bombay).

"First, we have the working class, which because of the principle of population is always too numerous relatively to the means of subsistence alloted to it — ie. over-population due to underproduction. Second, we have the capitalist class, which as a consequence of the same principle of population is always able to sell back their own product to the workers at such a price that they get back only just as much of it as is necessary to keep body and soul together. And third, we have an immense section of society which consists of parasites and self-indulgent drones, in part masters and in part servants, who appropriate gratuitously a considerable quantity of wealth — partly under the name of rent and partly under political titles — from the capitalist class, paying for the commodities produced by the latter above their value with the money they have taken from the capitalists themselves. The capitalist class is spurred on in production by the impulse towards accumulation; the unproductive classes, from the economic point of view, represent merely the impulse towards consumption and prodigality. And this is the only means of escape from overproduction, which exists alongside overpopulation relatively to production. Over-consumption by the classes standing outside production is (recommended) as the best remedy for both overproduction and overpopulation. The disproportion between the working population and production is neutralized by means of the consumption of a portion of the product by those who do not produce, by idlers. The disproportion represented by the overproduction of the capitalists (is cancelled out) by the overconsumption of the extravagant rich."

HEALTH AND MEDICINE UNDER IMPERIALISM

Imperialism is the highest stage of capitalism wherein monopoly capital dominates the life of society. Monopoly capital leads on the one hand, to a tremendous development of the productive capacity of human society, the spread of relations of wage-labour and capital throughout the world; but on the other hand, the private monopoly over these productive forces leads to its underutilisation its distorted development and the domination of one country or a group of countries over others either in the form of colonialism or otherwise. What are the *specific* effects of this phase of capitalism on health (the determinants, dynamics and the status of health) and Medicine (medical knowledge and medical profession) ? In general, the contradictions of capitalism between development of productive forces in society and the specific capitalist relations of production get accentuated in the period of imperialism. Thus the tremendous development of productive forces in the period of imperialism makes it more and more unnecessary for ill-health to continue to prevail. Moreover this development makes it more and more possible to improve health in a positive sense. But at the same time, capitalist relations of production in the imperialist phase do not allow full utilisation of this possibility. This can be seen from only a limited improvement in the provision of food, water, sanitation, safe working environment, medical care, to all the people in the world. Further, monopoly capitalism affects the development of productive forces in such a manner that they instead, foster ill-health by creating malnourishment all over the world (overnourishment in the imperialist countries, and undernourishment in the peripheral countries); pollution-creating and accident-prone working environment, disease creating medical interventions and so on.

This contradiction is also seen in medicine. On the one hand there has been a fantastic development in the medical knowledge leading to increased possibility of preventing and treating diseases. But on the other hand, the character of medical service as commodity (though often paid through social insurance) continues to limit its usefulness and this increasingly costly commodity is not adequately available to vast sections of the population who cannot afford to pay for it. Even the development of medical knowledge and of the profession itself has been vitiated by the narrow interests of those in charge of this knowledge and the services. Thus for example there is comparatively less research on the health problems of the people in the peripheral countries; inspite of the rise of preventive medicine, clinical medicine continues to dominate the scene; sexism, racism, expertism continues to affect the character of medicine. Medicine has also played an increasingly important role as one of the ideological supports of the ruling class (Ehrenreich, 1978). For example, medicine gives "scientific" credibility to the ideas of the ruling class that diseases are caused by germs, ignorance, bad habits and "ofcourse" poverty for which people themselves are to be blamed, and that ill-health can be got rid of if people become wiser, learn to live clean, give up bad habits and listen to the advice of the medical experts. Medical health care programmes have been used to diffuse class tensions.

Imperialism has developed through two distinct phases, from 1880's to 1945 is the colonial phase, wherein imperialist domination required direct political rule. The post-war period has seen the development of a new phase in imperialism with a distinct change in the structure of imperialist centres (rise of multinationals, of state intervention and so on) in the international division of labour and rise of politically independent bourgeois regimes in peripheral countries. We have to analyse health and medicine in both these phases.

Health in the Imperialist Countries

After 1870, in countries like UK, the incidence of infectious diseases and of diseases of malnourishment started a secular decline, thanks to the rising living standards and some public sanitary measures. But the mortality and morbidity declined much more slowly among the working classes. A substantial section of the population was still undernourished. Thus as late as 1930, a study in UK showed that out of six categories of population according to their income, only the two most prosperous had adequate diet (Doyal and Pennel, 1979). Even in 1970s and 80s some undernourishment continued in some working class sections of the population. But gradually food consumption had increased and this along with better sanitation, housing, and

other facilities decreased the morbidity and mortality due to infectious diseases. It needs to be noted that the impact of cheap grains and other food products from colonial countries enabled monopoly capital to offer concessions to the working class through an improved food basket, without much rise in the money wages.

The secular decline in undernourishment in the imperialist countries was, however, replaced by a new form of malnourishment, overconsumption, thanks to the rise of monopoly agri-business especially after the second world war. Production of concentrated foods stuffed with calories by reducing its fibre content is the way of increase its value per unit of weight and the surplus value (profit) contained in it. This low fibre, high caloric-density food led to the problem of constipation and a host of intestinal diseases related to it on the one hand, and the diseases due to overweight, cardio-vascular diseases on the other (Doyal & Pennel 1979).

Monopoly capital gave rise to a whole variety of new industrial products and processes. The technology to control pollution has, however, developed at a much slower rate since capitalists are primarily interested in profits and not in the health of the people. As a result, the workers and people in the neighbourhood were exposed to a new variety of pollutants, many of them being carcinogens. A new set of "industrial diseases" have sprung up.

Monopoly capitalism breeds consumerism. Even those products which are harmful to health are pushed onto the consumers through high pressure salesmanship which is characteristic of monopoly capitalism. For example, cigarettes, individual transport instead of efficient public transport, use of drugs and medical equipment when not indicated, and so on.

All the above tendencies are seen in a more sharpened form in the *post-war period*. The hazards of nuclear power reactors is an additional phenomenon. Increased alienation, psychological stress and strain has resulted in a higher incidence of psychiatric disorders as indicated by the fact that in England, 50 percent of the National Health Scheme expenditure is now used to provide psychiatric care of one kind or another (Doyal & Pennell, 1979). Massive state intervention in the economy is the specific feature of post-war capitalism. This has however not basically changed the process of social production of ill-health; state intervention has not been able to control the process of overnourishment, pollution, accidents and psychological stresses, generated by the incessant drive of the capitalist class for capital accumulation.

Two imperialist world wars figure as two dark patches in this otherwise not so happy scenario. Millions and millions perished, crores got injured, maimed, uprooted. Undernourishment, infections raised their heads once again. These and other effects turned the clock by decades.

Health in Peripheral Countries

What has been the effect of imperialism on the health of the people in the peripheral countries? The deleterious effect has been manifold. Wars of colonial conquest and inter-imperialist rivalry left many natives dead, injured and maimed. The ravages of war, the decline in availability of food, social disruption also took their toll in health.

The impact of the policies of the colonial masters have been studied by some researchers. Study of Africa offers a typical example (Turshen 1977, Doyal with Pennel 1979). Alongwith the conquest by western imperialists came a host of infectious diseases carried by the invaders from the pool of infection in Western Europe (Doyal with Pennel, 1979). The imposition of high taxes in cash and commercialisation of agriculture led to widespread poverty and reduction of availability of food; the migrant labour system, plantations, and the filthy, newly-industrialised towns led to epidemics, premature deaths, venereal diseases and alcoholism. The extreme degree of exploitation with scant regard to the health of the workers in the cities gave rise to a high incidence of industrial diseases (Elling 1981) and high incidence of infectious diseases. In the rural areas, indiscriminate tampering with the local environment led to epidemics of sleeping sickness, malaria and other diseases.

In the *post colonial period*, inspite of the faster tempo of the development of productive forces in the newly politically independent states the living-conditions of the labouring people did not improve, except for a section of the working class in the cities. Eradication of plague, small-pox; decline in cholera, malaria (in other words, those problems which are primarily amenable to technological solutions) have increased the average longevity. But there are medico-social and new health problems begging solutions. Those polluting industries which cannot now be tolerated in the West due to increased popular resistance to pollution have been exported

to the peripheral countries. Newly created irrigation-systems have led to malaria, filaria and Japanese encephalitis in certain parts of India (PPST Bulletin, 1984). Unplanned use of pesticides in the strategy of green revolution has increased the problem of mosquito resistance to D.D.T. Dams have increased the incidence of bilharziasis in places like Egypt. A series of wars amongst peripheral countries have benefited the imperialists at the expense of the health of the people.

Concentration of world food production in the imperialist countries after the second world war and the dependence of peripheral countries on food imports from abroad has converted the food situation into a political issue. The sudden withdrawal of the US food "aid" component in the seventies led to wide spread hunger, death, malnourishment in Sahel, Bangladesh and elsewhere. The health of the people in those countries which are now dependent on food imports is now at the mercy of the imperialists.

Medicine Under Imperialism

What have been the characteristics of Medicine in the period of imperialism? It is only after the 1870s that clinical medicine acquired some solid scientific formulation. All the branches of scientific clinical medicine have grown very rapidly during the last 100 years. But at the same time, medicine became more and more synonymous with clinical medicine since the character of medical services remained primarily in the form of sale and purchase between individual doctor and the patient. Though the sanitary and social reforms were almost solely responsible for the improvement in the health status of the population, clinical medicine and the "germ theory of disease" usurped the pride of place in the ideology of medicine since the vested interests of the clinicians demanded this. With the establishment of scientific clinical medicine a final, decisive onslaught on the traditional medical system as well as homoeopathic system was made through the famous Flexner report in the US which argued for allowing only "scientific medicine" (meaning clinical medicine with all the limitations imposed by the commercial professionalism of male doctors) to continue. Scientific clinical medicine, however, arrived too late on the European scene since most of the infectious diseases had already declined substantially and medicine had hardly anything to offer on the new health problems. The post-war period saw a new explosion of scientific knowledge. In the absence of a proper social perspective, and a conducive structure of medical profession, this new knowledge led the ideology of superspecialisation and expertism.

The discipline of "public health" in the mid-nineteenth centrury grew into a modern science of Preventive and Social Medicine (PSM) and still further into Community Medicine in the twentieth century. But firstly this all important approach has been relegated to secondary importance by the medical-industrial complex. Secondly, the established discipline of PSM has neglected or rejected the Marxian approach, is informed by bourgeois sociology and hence it has hardly any correct understanding of the relation between health and the process of capitalist development, of the changing balance of class forces. Its scientific insights are marred by its bourgeois paradigm/framework and hence cannot challenge bourgeois social order. Nay more — it tends to create illusions that ill-health can be eliminated through technical interventions applied on a social scale. Through concepts like "tropical diseases", "diseases of industrialisation", PSM *naturalises* the cause of diseases which are primarily of *social* origin. It has thus a kind of fetishistic understanding of the diseases and hence has become a part of bourgeois ideology.

The specific effect of monopoly capitalism has been the rise of monopoly medical industrial complex. The monopoly drug corporations, medical equipment corporations and health insurance corporations have joined hands together (with the doctors acting as accomplices) to exploit the people, to breed consumerism and help keep the labour-force docile and productive. Some medical insurance companies like Metropolitan Life, Providential have grown larger than General Motors and Standard Oil. Unncessary medical interventions at each stage of life; ("from womb to tomb") this medicalisation of life (Illich 1976) is a specific feature of this stage of capitalism.

Special mention needs to be made of the drug companies. The explosion of antibiotics and other "wonder" drugs after the second imperialist world war is hailed as one of the greatest achievements of n odern medicine. But these drugs which can contribute a great deal to relieve pain and sufferings, are not available to the poor. Secondly, an illusion is being created that medicine can solve the healthy problems of society with the help of these "wonder" drugs. The potential created by modern sciences like chemistry and pharmacology is being used to exploit people and create illusions. There is plenty of literature available on this issue.

Thus the heightened capacity of medicine in the period of monopoly capitalism has not only been limitedly used, but the capacity itself has been affected by monopoly capital.

Medicine and Imperialist Domination

What has been the role of Medicine in the imperialist domination over the peripheral countries? In the colonial period, medicine helped the conquest of colonies. Some of the infectious diseases like yellow fever and malaria, took a heavy toll of the imperialist army and hence made it impossible for the army to win territories. Medicine solved this problem by controlling these diseases (Brown 1978, Doyal and Pennell 1979). But, those diseases which exclusively affected the natives were not controlled in this period. Secondly, effective curative services offered by missionary dispensaries created a good impression on the natives; and distracted their attention from the ill effects of colonialism. In the words of the then president of the Rockfeller Foundation, "Dispensaries and Physicians have of late been peacefully penetrating areas of Phillipines Islands and demonstrating the fact that for the purpose of placating primitive and suspicious peoples, medicine has advantages over machine guns." (Brown 1978).

Later, the imperialists initiated health programmes for the natives to improve their health and thereby their productivity. Increased productivity meant increased profits for imperialists. For example, the Rockfeller Foundation programme to control hookworm infestation in Latin America (Brown 1978). Such health-programmes also offered them opportunities to export drugs and equipment. Problems like tuberculosis, leprosy, venereal diseases cannot however, be eradicated by such techniques of social engineering because they are much more deeply rooted in the social structure of peripheral capitalist countries. Colonialism has also led to the suppression of indigenous systems of medicine.

In the post-colonial period, it is well known as to how the imperialist domination in the field of medicine over politically independent countries continues in an indirect form through the multinational drug companies, through population control programmes and other "health programmes". The role of western dominated medical education is also important. Western dominated medical education in peripheral countries produces doctors suited to work in imperialist countries. This enables imperialist countries to import medical graduates from peripheral countries and save money which would have otherwise been spent on training doctors in their own country. This "brain drain" is also a financial drain since peripheral countries spend so much on training these doctors here. Moreover, the illusion that health problems of your society can be solved through medical interventions carried with the help of 'superior and benevolent" west, the ideology of medical expertism percolates through this type of medical education.

The period of rapid growth of peripheral capitalist societies after political independence came to an end in the late sixties. As a part of its response to this crisis, the ruling class is changing its strategy of medical care. The cost of medical care is sought to be reduced through the scheme of village health workers. New innovations in the management of health problems are being used to create illusions under the slogan of "Health for all by 2000 AD". The talk about "indigenous" system being made more suitable than "Western medicine" needs to be understood in this context. There's hardly an adequate attempt to really find out and develop the useful, rational aspect of indigenous systems of medicine. The continued neglect of these systems shows that the hollow praise bestowed on it is only a part of the new strategy of dumping responsibility onto the people for their health.

A struggle to create a healthier society and an appropriate system of medical care cannot be separated from the struggle against imperialism. In this struggle, the aim cannot only be taking over the existing productive forces, the existing medical system and using it in the people's interests. How can people in a socialist society be healthy if they consume the same amount and type of food as is being done in the US today or get their electricity from nuclear reactors? Likewise imperialism has also vitiated the science of Medicine. How exactly and to what extent this has happened is a matter of further study. A word of caution is in order here. Let us not fall into the opposite pitfall of rejecting the relevant scientific advances made by medicine in capitalism. One cannot talk in terms of modern medicine as such and reject it. Rather its a question of grasping the rational kernel of existing medicine and developing it further Otherwise, we would throw away the baby with the bath water.

In This Issue

Radhika Ramasubban examines the colonial health policy in India and traces its legacy to the present public health system. Meera Chatterjee highlights the wide ranging implications of a new scheme formulated by the American Association of Physicians of Indian Origin in collaboration with the IMA to transfer high technology in medicine to India. Warren Salmon's reprinted article deals with the increasing interest and involvement of large US corporations in health issues in America and the emerging class stand which will eventually restructure the health sector under monopoly control. The article on racism and health in the US, a revealing glimpse at health care in a country which spends one billion a day on such care is by Bindu Desai a neurologist working in the Cooke Country Hospital in Chicago. The *Bhopal Update* which is likely to be a regular feature in future issues is a resumme of health issues, health efforts and on-going medical debates concerning the Bhopal disaster by Padma Prakash. We feature a review article on John Braithwaite's explosive new book on the drug, industry, *Corporate Crimes in the Pharmaceutical Industry* by Ravi Duggal. This book is a must for all concerned people — if one can afford the price !

SORRY :

Due to oversight the box requesting for subscription renewals (1:4,p.144) quotes the new subscription rates as Rs. 24. Here's some good news! The subscription rate **remains at Rs. 20 (for four issues).** We have increased the price of **individual copies to Rs. 6.** Do send your renewals and PLEASE write your name and address on the counterfoil of MOs --- we would prefer cheques or demand drafts drawn in favour of Socialist Health Review.

INVITED :

Requests for SHR First Issue

It's not really a collector's item, but we do have queries and requests pending for the inaugural issue now out of print ! We cannot, however reprint the issue unless we have orders for a sufficient number. If you would like a copy please write to us urgently. If we receive orders for more than 200 copies we will be able to supply copies at Rs. 10 each. If not, we can get the entire issue photocopied at Rs. 25 per issue. Please let us know if you would like a copy at this latter rate or only if it is available at Rs. 10 each.

Centre for Education and Documentation

The CED collects, collates, researches and disseminates information on a wide range of subjects of social importance. The following publications are available with us :

Counterfact (CED Health Cell Feature)

1. Abuse of Female Hormone Drug — No. 1
2. Bleeding for Profit — No. 2
3. Injectables: Immaculate Contraception? — No. 3
4. Health and the Work-place — No. 4
5. Asbestos -- The Dust that Kills
6. Health Sans Multinationals : The Bangladesh Crusade
7. Pills for All
8. ORT and the Credibility Gap

Research Publications

1. Aspects of the Drug Industry in India -- *Mukarram Bhagat*
2. Operation Flood : Development of Dependence -- *CED Research Team*
3. Land Degradations : Indian's Silent Crisis -- *Mukarram Bhagat*

THE COLONIAL LEGACY AND THE PUBLIC HEALTH SYSTEM IN INDIA

radhika ramasubban

Colonial health policy in India never really came to grips with the problem of public health. Through the evolution of a 'colonial mode of health care', the enclave sector — the army and the European civilian population —— kept pace with the metropolitan developments in sanitary and medical sciences while attempts to introduce epidemic control and public health measures remained abortive. In the last years of the nineteenth century when the situation afforded a compelling basis for a far-reaching public health policy, the colonial government found an escape route in the new research possibilities. The contradictions of the health system in India arise from its historical legacies. This article traces the various strands which evolved during the period of colonial rule and the manner in which they continue to shape the present public health system.

This article is an abridged version of an earlier research report by the author, "Public Health and Medical Research in India. Their Origins under the Impact of Colonial Policy" (SAREC, 1982).

The task of tackling widespread disease and of raising the health status of the population requires coming to grips with the conditions which cause debility and disease. The three main instruments for such a strategy in the Indian context are thoroughgoing public health measures, improvements in the standard of living of the population through raising incomes and providing employment and making the health services available to those in need. Obviously, the health system alone cannot cope with all these challenges and in a general sense the contradictions of the Indian health system are a reflection of the contradictions of the development process itself. More specifically, the contradictions of the health system in India arise from its historical legacies and the overall framework which guides its nature and functioning.

India missed going through the period of sanitary reform which swept through most of Europe in the 19th and early 20th centuries. Colonial health policy never really came to grips with the problem of public health in India, whereas through a policy of segregation and what evolved into a 'colonial mode of health care', the enclave sector — the army and the European civilian population — kept pace with metropolitan developments in sanitary and medical science. In the absence of general public health measures, epidemics of small pox, cholera, plague and influenza continued to recur among the general population. Some attempts made in the first quarter of the 20th century to evolve epidemic control measures remained abortive due to the administrative disruptions caused by the two world wars and the preoccupation with the health of the army, particularly the control of malaria in the eastern theatre of the second world war.

The independent Indian State, although it recognised public health as one of its main concerns, lacked the commitment to carry through a public health revolution. Seen in the wider historical perspective, the huge expenditure that public health measures require have been incurred by the State in the western countries for ensuring a steady supply of the labour force and for raising its productivity. The capitalist path of development launched in India has remained distorted and slow. It could neither impart dynamism to the public health system as it had very little demands to make, nor could the productive forces develop to the extent which would improve the health status of the population by meeting their nutritional and other basic needs. About half the Indian population is still living below the minimum nutritional standard for meeting the energy requirements of the body and the incidence of diseases preventible through public health measures dominates the disease profile.

The problem with undertaking far reaching public health measures such as protected and adequate water supply, sewerage systems and better housing and nutrition is that it requires massive public expenditure. The independent Indian State, however, has not been able to meet these requirements (Ramasubban, 1984). It has, instead, settled for softer options which are essentially a continuation of the colonial tradition. The attempt here will be to trace the various strands that evolved during the period of colonial rule and the manner in which they continue to shape the present public health system.

The Evolution of Colonial Health Policy

The main factors which shaped colonial health policy in India were its concern for the troops and the European civil official population. The response

to this concern underwent a series of stages corresponding to the growth of knowledge in England about the principles of disease causation. The old climatic theory was that the Indian climate caused diseases in the 'abdominal cavity' while that of Europe caused disease in the 'thoracic cavity' (Scott, 1939). This gave way to the theory of miasma, resulting in a policy of segregation and sanitation which began in the mid-nineteenth century and continued through until the end of the century. The result was the evolution of a distinctly colonial mode of health care. This policy also took into account statistical patterns of mortality and simple prediction of epidemics. The general spread of epidemics resulted, however, in the mobilisation of international opinion, and the perception of the Indian population as a secondary source of infection brought the general population into the ambit of health policy. But the main concern remained the army, and therefore, the evolution of colonial health policy has to be necessarily placed within the framework of the army. The shift in focus in England and Western Europe from sanitation to epidemiology and bacteriology, which began in the 1880's and gained revolutionary momentum in the following decades, had significant implications for India. By the turn of the century, laboratory investigations were instituted in the four army commands, to put army health on modern, scientific principles. Although the direct link between health and medical research remained confined within the framework of the army, the growing interest in, and official patronage for the discipline of tropical medicine in England integrated India, the largest natural disease laboratory in the British empire, into metropolitan scientific activities; and a few laboratories for research were set up within the country.

The army, the main instrument of the East India Company's political consolidation, was primarily composed of Indian soldiers, the European component being outnumbered by roughly eight to one (Imperial Gazetteer of India, 1909). The high cost of transporting European soldiers to India and of invaliding due to sickness, and the time taken in further recruitment and replacement, were the major factors responsible for the excessive reliance on the Indian component.

Mortality, sickness and invaliding in the European army was due mainly to four major diseases: fevers, dysentery and diarrhoea, liver diseases and epidemic cholera, in that order, all of which, particularly the last-mentioned, assumed virulent form when the troops were on the march. And the troops were almost constantly on the march in the prevailing unsettled state of the country.

As regards the European civil population, a large section was concentrated in the three Presidency towns of Calcutta, Bombay and Madras, which were centres of government as well as the major ports. Here European areas of residence were secluded from the Indian areas and along with the cantonments in these towns, were fully self-contained. By the mid-nineteenth century, these areas were relatively well planned and drained and vaccination against small pox (the only effective prophylactic known), among the European civilian residents and among the residents of the cantonments, was almost universal.

The events of 1857 — the 'Indian Mutiny' — highlighted as never before, the importance of the British soldier's health and efficiency. Army health which became the primary concern of colonial health policy remained an abiding concern as, with the expansion of the British empire, the army in India increased in importance as the largest single force in the empire, and as a key instrument in the security of Britain's eastern possession. The 'Mutiny' of 1857 had highlighted the insecurity of British military power in India. Reliance had hitherto been placed on Indian soldiers and they had vastly outnumbered the European component. Although the majority of the Indian troops had remained loyal to the Company and the 'Mutiny' had been successfully quelled, it was decided that the defence of India would henceforth have to be in British hands, and it was resolved that the 'British army serving in India' should form part of the Imperial British army. This necessitated the transfer in 1858 of the European troops of the East India Company to the Crown and a Royal Commission was appointed to work out the army's reorganisation. It recommended raising the number of British troops, and that the ratio of Indian and British soldiers should be of the order of 2 to 1. The result was a 60 per cent increase in the number of British troops. (Imperial Gazetteer of India, 1909)

The result of the increase in the strength of British troops was that one-third of all British forces came to be stationed in India. The problems in acclimatising such large numbers to Indian conditions and ensuring their health, therefore, assumed importance.

Along with the Indian Mutiny, the Crimean war, too, played an active role in focusing discussion in England on the health of the British army. The

Crimean experience had shown that mortality among troops had been due primarily to epidemic ravages and the insanitary state of barracks and hospitals rather than to wounds of war. It highlighted the need to apply the principles of modern sanitary science currently championed in England by sanitarians like Chadwick and John Simon, to the army. In 1857, a Royal Commission was appointed to enquire into the regulations affecting the sanitary conditions of the army, the reorganisation of military hospitals and the treatment of the sick and wounded. The enhanced strength of the British army in India required a similar enquiry into Indian conditions, and in 1859, another Royal Commission was appointed to enquire into the Sanitary State of the Army in India.

Of the total number of deaths in the period examined by the Commission, i. e., 1817 to 1857, only 6 per cent had been due to war. The rest were caused by four major diseases : fevers, causing about 40 per cent of all deaths and three-fourths of all hospital admissions; and dysentery and diarrhoea, liver diseases and cholera being the other killers. Fevers, besides the suffering and immediate risk to life, also had a tendency to relapse dangerously and affect vital organs, resulting in considerable subsequent illness, mortality and invaliding among British troops. At this time 'fevers' was still a general term for most forms of sickness. Clearly, therefore, "the main enemy of the British soldier in India was not the Indian enemy but disease". (Royal Sanitary Commission Report, 1863).

a) Sanitary principles and the policy of segregation.

The situation, however, was neither unfamiliar nor irremediable. The old climatic theory had held that the Indian climate produced diseases distinctly different from those resulting from the English climate. Now, the diseases which were fatal to the British soldier in India were recognised as familiar, as those which had until recently caused the highest mortalities in England, and which had been brought under control in that country through sanitary programmes.

The keynote of metropolitan sanitary science, which grew out of the compulsions of urbanisation in England in the eighteenth and nineteenth centuries, was environmental control. The means through which this was accomplished were mainly town planning, housing and sanitary engineering. These measures required administrative and government institutions embodied in 'local governments', which were responsible for investigation of local insanitary conditions and their control, and given the force of legal sanction through public health legislations.

The physical placement of the European population in India was, as far as possible, based on the principles of this sanitary science. Using criteria of soil, water, air and elevation, the Royal Sanitary Commission on the army in India laid down elaborate norms for the creation and development of distinct areas of European residence, and the 'cantonment', 'civil lines', 'civil station' and 'hill station', regulated by legislations, developed into a colonial mode of health care and sanitation based on the principle of social and physical segregation. From the time of the Royal Commission's Report of 1863, the location and layout of European civil and military areas were determined by criteria of health laid down by the prevailing medical scientific theories of miasma and environmental control rather than by political and strategic criteria. Most of the troops were located at 'hill stations' or on elevated ground. In cases where strategic stations were unhealthy, only small forces were posted there to be reinforced at short notice. Earlier, the 'native lines', i. e., residential areas of Indian soldiers, had been left outside the pale of colonial planning and construction activity for troops. European fears of miasma emanating from them had even led to construction of walls between Indian and European troop locations to keep the miasma out. The Royal Sanitary Commission voiced concern for the health of the Indian troops and recommended that cantonment planning should also be extended to the 'native lines'.

b) Public health machinery : vital statistics and disease control

Following the Royal Commission's Report, Cantonments Acts, Regulations and Codes were issued modelled on public health acts in Britain.

While segregation was an effective tool, at least in the three Presidency towns contact with the native population was unavoidable. Native servants often lived in the native areas, and native dealers and tradesmen serviced the cantonments and civil lines. Grossly insanitary conditions prevailed in these large and unplanned urban centres and the native population could well serve as secondary sources of infection. An understanding of disease among them was, therefore, considered essential. In his despatch to the Government of India the Secretary of State for India pointed out, "The determination of the effects of local causes on the mortality of the

native population, besides its intrinsic value in connection with the welfare of the people of India, cannot fail to have an important bearing on the health of the Europeans resident among them." Gazette of India, 1864).

Three Presidency Sanitary Commissions were set up in 1864. The basis for the functioning of these Commissions was to be the systematic generation of facts about mortality, epidemics and sanitation, which would be embodied in an annual sanitary report to be submitted to the Government of India by the Sanitary Commissioner to the Government of India. This would in turn be summarised in annual reports presented to parliament on the progress of sanitary measures in India. This laid the foundation for a public health machinery, particularly in the field of vital statistics and disease control.

The investigative tradition was an integral part of the sanitary movement concurrently taking place in England; in fact, the first stage of the public health movement was that of governmental investigations on grand scale. Regular statistical reports were also seen as essential to any systematic public health control and since the establishment of the office of the Registrar-General of Births, deaths and Marriages in 1836, the steady accumulation of statistical evidence had generated a demand for further research into the causes of epidemic diseases. (Shryock, 1948)

In keeping with this tradition, the Government of India appointed in 1861, the first systematic enquiry into a major epidemic — the cholera epidemic of 1861. The facts that it highlighted were followed up in the annual sanitary reports, which resulted in a steadily growing volume of statistics and facts about the disease.

The significance of the 1861 epidemic was that its impact was not confined to India alone; it was followed by another epidemic in 1865 which spread from Egypt across Europe to England. Cholera had been the most important factor responsible for initiating the public health era in Britain in the early nineteenth century. The 1861 epidemic provided the final and most powerful spur to sanitary legislation in England. This was the Sanitary Act of 1866 embodying the important principle of compulsion by the central authority if the local sanitary authority failed in its duty.

This epidemic also gave rise to four international sanitary conferences participated in by European countries in 1866, 1874, 1875 and 1885. They devoted their deliberations specifically to this disease and attempted to work out quarantine measures acceptable to all participating countries; systematise existing knowledge about the disease and identify major questions for further investigation; and, recommend measures for prevention. As the 1861 epidemic had originated in India, the first Conference at Constantinople discussed India as a major topic.

The Constantinople Conference put the Imperial government into a quandary by pronouncing India the natural home of cholera. In the absence of any breakthroughs in know edge about the cause and mode of infection, the Conference stressed the need for stricter implementaion of rigorous and lengthy quarantine both in sea and land movements, greater cleanliness and disinfection of ships, houses and merchandise, and care to avoid overcrowding. The central consensus of the Conference was that the spread of cholera epidemics was due to rapid movements of groups of people and their personal effects, water and food supplies. It pronounced that in the case of India the movement of pilgrims and large congregations at fairs and festivals was the single and "most powerful of all the causes which conduce to the development and propagation of epidemics of cholera". (Cholera Committee Report, 1867). In the opinion of the Conference when the pilgrims congregated, the cholera spread among them and when they dispersed they carried the contagion with them over long distances. The Conference recommended elaborate preventive, sanitary and curative arrangements at pilgrim centres and on pilgrim routes.

The international arrangements outlined for quarantine and the recommendation proposed regarding pilgrims, by the Constantinople Conference, were particularly irksome to Great Britain which had the largest international maritime trade as well as the most frequent troop and naval movements to and from its colonies. In the face of stricter quarantine restrictions imposed by the Constantinople Conference and the international pressure to control cholera within India and prevent its spread therefrom, Great Britain responded by instituting its own investigations into the authenticity of a quarantine policy, i. e., whether it was local conditions of soil, air and water rather than contagion carried through people and their effects which caused the spread of epidemics, and whether there was a possibility of coping with cholera through effecting sanitary

improvements rather than quarantine. Professional medical opinion in England also provided support to such a move and a special enquiry came to be sanctioned by the Secretaries of State for War and India into the mode of origin and transmission of cholera.

While the results of the scientific investigation were being awaited, practical sanitary measures were intensified in relation to all cantonments, smaller military stations, troops on the march, jails, hospitals and seaport towns. By 1872 local medical officers in all the various military stations were doing simple qualitative analysis of water. The prohibitions upon soldiers going into the Indian cities or cholera affected areas were more strictly enforced and "sanitary cordons" (suggested by the Constantinople Conference) were erected around cantonments to prevent persons residing in nearby villages and localities and those suspected of carrying cholera, from entering the area. Infected cases in cantonments were isolated and barracks, jails and hospitals fumigated.

Hitherto, troops on the march had been the most vulnerable to cholera attacks. The new sanitary rules governing the marches also included rules regarding railway travel, such as provision of good drinking water and wholesome meals at halting stations, isolation of the troops from the native towns and bazaars en route and at destination, thirty-minute stops every four hours and travel for not more than twelve hours at a stretch.

Systematic statistics about cholera were accumulating with the regular publication of annual sanitary reports. These statistics pointed to direct personal contact as an extremely unlikely cause of infection Nor was land quarantine doing much good; and nor did cholera appear to travel along highways and major lines of communication. As regards sea travel, however, stricter control was instituted, mainly in deference to international pressure.

Until the end of the 1880's, cholera of all diseases pressed most heavily on British soldiers in India, being the most important cause of mortality although not adding significantly to the sickness rates. The investigations of Lewis and Cunningham, by going into the question of sub-soil water levels, had launched on a relatively fruitless line of enquiry which failed to produce conclusive evidence on the cause of cholera. But although their study (Lewis and Cunningham, 1876) made little impact on the control of cholera, it was valuable in that it stressed the importance of looking elsewhere than into, contagion through personal contact. But by the period 1870-79, the combined effect of sanitary measures and other reforms had brought average mortality due to all diseases among European troops down to 19.34 per 1000 of strength, of which cholera accounted for an average of 3.22 (calculated from Annual Sanitary Report for relevant years). By the end of the century the severity of cholera came down even further and after 1900 rarely one person in 10,000 among the European troops came down with cholera (Annual Sanitary Reports, 1899-1929).

The year 1883 was one of the major landmarks in scientific investigation into disease causation. A German Commission led by Robert Koch discovered the Cholera 'Comma' Bacillus in Egypt and visited Calcutta in the same year to confirm the discovery. Koch's discovery was a significant contribution to the germ theory of disease causation which had emerged in Western Europe in the 1860's and studies like his and those by Pasteur, which linked a specific organism with a specific disease, helped to firmly establish the theory in the 1870's and 1880's. This modern scientific revolution in medicine challenged and ultimately triumphed over the earlier miasmatic theories.

c) General Population

The Constantinople Conference's declaration of India as the source of epidemics, its condemnation of the British government for failing to control these epidemics and the latter's own recognition that the Indian population constituted a secondary source of infection, provided the compulsion for broadening the scope of health policy and include the general population in its purview.

In keeping with the theory of contagion, the places of pilgrimage and pilgrim routes became the starting point of health policy in relation to the general population, and the formal motions of attending to the problem were gone through. Committees were appointed and reports prepared. But when it came to giving a concrete course to the policy, however, the government's attitude remained evasive.

While the suggestions of the Constantinople Conference regarding the desirability of sanitary precautions in relation to large groups of people on the move was quickly given effect in the case of troops on the march. In order to prevent

the outbreak of epidemics among them, the question of epidemics at the pilgrim centres was treated as a puzzle, and various other considerations such as finance, religion and race clouded the issue. However, at the 1867 Kumbh Mela, the government as a test case made some ad hoc sanitary and hospital arrangements. These had proved successful in curbing cholera on the fair grounds. But no sooner had the pilgrims dispersed, than the cholera that they carried spread in the regions through which they passed and in their ultimate destinations even as for as 700 miles away. This seemed to imply that not sanitation alone but land quarantine measures were required. The official position was to see this as an intractable problem, for quarantine was not considered to be a feasible measure in the case of people who would be dispersing over a large area. The response of the Government of India was to rest content with the prohibition of pilgrims from entering military stations or even their neighbourhood.

In fact, the whole question of pilgrims taking cholera back with them to their towns and villages raised the uncomfortable issue of an extensive public health machinery for the general population on a continuing basis, which would be the only countervailing force against epidemic cholera emanating from pilgrim movements and congregations.

But sanitary reforms were expensive and unremunerative. The MacKenzie Committee appointed to go into the pilgrim question recommended that the government should undertake the responsibility for at least a few such measures at pilgrim centres. If public health measures for the general population at large could not be adopted, at least the enforcement of conservancy measures at fairs and pilgrim centres and demonstration by the government thereby of the desirability of sanitation would act as an incentive for the general population to voluntarily adopt the modern sanitary principles in towns and villages. The Committee argued that such a step was also in the interests of the European population. But the government rejected the idea of expenditure on conservancy measures and sanitary police at pilgrim centres, and policy floundered on the issue of whether pilgrims should be made to pay for sanitary arrangement through a sanitary tax. (MacKenzie Committee Report, 1868)

Progress on sanitary reforms concerning the general population was blocked on the ground that no measures could be enforced, as any element of compulsion would offend the people's religious sensibilities and be construed as interference in their customs. The bogey of interference in the religion and customs of the people was not new, but was more self consciously applied after the 'Mutiny.' Eighteenth century East India Company officials many of whom recognised in India a superior civilisation, had been replaced in the early nineteenth century by administrators who saw their mission as 'civilizing' and 'modernising' Indian society. Indian society was seen as a *tabula rasa* waiting to be recast in the Western mould. The civilising influence would be Western social and economic institutions and Western religion, i.e., Christianity. After the 'Mutiny', however, the enthusiasm for remaking Indian society declined. The climatic and socio-religious theories gave way to theories of racial exclusiveness, as Britain established itself as the supreme governing power and as the European establishment in the country perfected the mechanisms of physical and social segregation. Indians now came to be seen as a distinctly inferior race incapable of appreciating or successfully adopting British habits and institutions. That interference in social and religious practices would offend Indian sensibilities, was only the rhetoric, offered for government inaction to bring into force a public health machinery and sanitary reforms in India along modern lines.

As far as the people themselves were concerned, the MacKenzie Committee which sought Indian opinion on the matter of sanitary measures at pilgrim centres, found that the people were willing to submit to any measures calculated to promote their health. There was also evidence that the arrangements at Hardwar in 1867 had suitably impressed the pilgrims.

While the government persisted in its evasiveness the railway companies, realising that pilgrims were good business, were cashing in on the age-old enthusiasm of Indians for undertaking pilgrimages. A large number of pilgrim centres existed across the country, and it was the aspiration of every Indian to visit at least one of these centres in his lifetime. There were also certain specific religious festivals which drew large numbers at certain times of the year. In the old days the journey used to be long and arduous and done on foot or by animal carriage. There were accepted pilgrim routes and halting places at villages en route where accommodation and food or facilities for cooking were available

Most of these were free and maintained by philanthropists.

The introduction of railways offered a universal opportunity for undertaking pilgrimages and the possibility of a single person perhaps undertaking several in his lifetime, and railway travel for this purpose became extremely popular. The railway companies responded quickly to this source of profit, offering return tickets and half fares for children. But the facilities were appalling. Pilgrims were stuffed into dirty goods wagons with no ventilation lighting, drinking water and sanitary arrangements on board. The doors used to be fastened from the outside and not opened for hours at a stretch, as allowing the pilgrims to climb in and out at stations en route would cause delays. The few third class carriages allotted for pilgrims were impossibly overcrowded. And for a long time no provision existed for clean accommodation, drinking water or meals at halting stations. Death from suffocation and disease in the goods wagons and cholera epidemics on railway journeys and at pilgrim centres became more frequent as the pilgrim traffic increased and the rapid communications spread disease more rapidly. Pilgrims now poured into holy places in much larger numbers than these places had been provided to cope with and problems of sanitation were further aggravated. Even as cholera had almost disappeared among the troops, epidemics continued to rage among the general population. The Committee which investigated the matter recommended that government move in to check the worst abuses of railway travel and regulate the conditions of pilgrim movements. conveying pilgrims in closed air-tight wagons meant for goods should be discouraged, eating houses at railway stations be licensed, and provisions made for drinking water and toilets at stations.

The salient feature of the pilgrim movement now was that the congregations of people did not take place only at certain times of the year; rather, the pilgrim centres had a constant flow of people round the year. Ad hoc measures, therefore, could no longer be considered an effective solution to the epidemic problem.

The last decade of the nineteenth century was a period of significant landmarks in determining the course of the colonial health policy. The two governing landmarks were the plague epidemic which broke out in Bombay in 1896 and the discovery in India by Ronald Ross of the Indian Medical Service of the mode of transmission in malaria in 1897. The responses to these two events reflected the growing complexity of Britain's international position and rise of British imperialism, Britain's perception of India's place within the Empire the internal changes effected by the Government of India to adapt India to its new role, and the contradictions within the Government of India's policy.

The neglect of public health measures among the general population; accompanied by the intensification of trade and commerce and the growth of population in the seaport towns; as well as the increasing impoverishment in the rural areas and the flow of migrants into the towns and cities in search of work; came to a head when the plague epidemic which broke out in Bombay in 1896 was followed by successive epidemics which spread the disease to large parts of the country, and which by 1918 had taken a toll of almost 10.5 million lives. What was striking was that all the plague deaths occurred only among the Indian population.

Plague was known to have been endemic to Europe since early times but by the end of the seventeenth century it had completely disappeared. When the plague broke out in Bombay, the spread of the epidemic within the city and to other parts of the country combined with the movements of destitute people out of the rural areas and into the towns due to the widespread famine, threw the authorities into a flurry of confused activity. The Bombay plague committee was set up on a crash basis for the period 1897-1898. In the absence of any scientific knowledge about what caused the disease it was treated as contagious. House to house searches were conducted with the aid of police cordons to register deaths and remove sick persons for isolation, dilapidated houses were vacated and disinfected and the inmates removed to camps, rural migrants to the city were detained in camps to prevent disease conditions exacerbating in the city, and at the railway stations passengers and their baggage were disinfected.

But these ad hoc measures were no solution to a situation which was rapidly getting out of hand. The single most important cause of bubonic plague was insanitation which created the conditions for a large number of rats to live in and around human dwellings, and poorly constructed, dark, ill-ventilated houses where rat fleas could take refuse away from air and sunlight which were their most effective killers. As long as drainage, sewerage and planned housing remained severally defective or non-existent, the plague, once introduced, would

continue to remain endemic. The transmission of the disease from the rat to man through the rat flea and not through human contact as in pneumonic plague (familiar to England as the 'Black Death') rendered isolation and detention camps useless.

The plague epidemic could have provided a take-off point for a more far reaching public health policy. True, the unreformed sanitary conditions among the general population exacerbated by the impact of colonial economic policies and natural calamities had worsened public health conditions. While the urban centres were undergoing a haphazard development, the countryside was becoming increasingly impoverished. But the result of the plague innoculation drives, the first major attempt at epidemic control, was the growing awareness of and desire for sanitary reform among the general population. Representations were made by Indians requesting the government to take the initiative in maintaining the struggle against the plague, and in widening the scope of sanitary reform. The need to create an effective public health machinery had also been unequivocally stressed by a body of expert scientific opinion from England who, in elucidating the mode of transmission of bubonic plague, had pointed to insanitation as the single most important cause, and had even drawn up a tentative scheme for public health administration.

The scheme remained unimplemented by the Government of India, and once again, the official response was the rhetoric of caution in quickening the pace of sanitary reform for fear of pressurising public opinion. In fact, as far as the government was concerned, the living conditions of the general population were "beyond the influence of sanitary effort..." (Annual Sanitary Report, 1900-01). Articulated public health policy was growing into one of leaving the Indians to their own efforts.

The plague epidemic and Ronald Ross' malaria breakthrough had been the thereshold for the developments between 1900 and 1935. A step could have been taken in the direction of focusing policy on evolving a public health machinery. However, the possibility of research also presented itself at this moment and the colonial government for its own reasons chose the latter option.

In England, the public health system had come into its own by the time of the scientific advancements in medicine, and the new stream of scientific ideas while they revolutionised health care, did not replace the public health machinery which continued to enjoy a relative autonomy. In India, the metropolitan sanitary science was addre ssed only to the colonial population resulting in what we had earlier referred to as a colonial mode of health care. It, however, had a demonstration effect on the general population, which began to see its potential in the last few years of the nineteenth century.

Public opinion was beginning to form the basis for a potential sanitary movement in India. The Indian elite showed eagerness to lay the foundations in the country for the growth of medical science in which Indians could participate and benefit therefrom. The various international sanitary coneferences and the British Plague Commission were an added source of pressure upon the colonial government to pay attention to public health.

Just at a time when the situation afforded the compelling basis for a far-reaching public health policy, the colonial government found an escape route in the new research possibilities, and public health policy as in the past remained sporadic and ad hoc. The Sanitary Department was most unpopular with the colonial medical bureaucracy and by the time sanitation and public health were made a provincial subject in 1919, the Sanitary Department already lacking a coherent policy or substantial financial provision, was depleted of most of its supervisory personnel. In the remaining decades of colonial rule nothing occurred to change this pattern. No single authority responsible for the efficiency of health measures throughout India came to exist, and nor was there any single Public Health Act as in England. The only concern of the Imperial Government was port quarantine. Vital statistics remained very defective due to the absence of a wide deployment of medical personnel.

With the superceding of the era of active sanitary reform by an era of emerging professionalisation in medicine in England, the consequences for Indian public health in terms of the lost historical possibilities were far-reaching. Medical education had been initiated in the Indian Presidency towns by the mid-nineteenth century, mainly to train hospital assistants for military and civil hospitals. The medical colleges also received a steady influx of Indians right from their inception. When the bacteriological advances of the late

nineteenth century put curative medicine on a scientific basis and led to its increasing professionalisation this served as an argument for colonial policy to encourage the expansion of the private medical profession (ooth European and Indian) — for a few medical colleges were a cheaper alternative to expending goverernment resources on sanitary reforms for the general population. The growth of preventive and social medicine was irremediably pre-empted and the rising medical profession made its spoils from the ever-expanding disease market.

The Present Health System and its Contradictions

The 'functional approach', which sees health as 'fitness' to undertake one's work as a productive member of society, and ill health as the result of malfunctioning of one particular part of the body which can be corrected through medical interventions, arose out of the conditions of maturing capitalist development in Europe in the 19th century, and achieved final consolidation with the development of the germ theory in the last two decades of the 19th century. (Doyal, 1979) But the functional approach could come into its own mainly on the strength of effective declines in mortality and morbidity due to the control of infectious diseases brought about by the State in the pre-germ theory era through effective public health measures which stressed the predominantly environmental — 'filth' or 'miasma' — causes of disease and death.

In India this functional approach, carried over from the experiments during the colonial rule, has remained partial and ineffective. In those spheres where the regular supply of skilled and physically fit manpower has been crucial, as for instance the army and capital - and technology-intensive sectors of the economy, the 'colonial mode has been the preferred pattern : social and physical segregation of employees and their families into exclusive residential areas or housing colonies with clean and sanitary environments, access to subsidised and good quality medical and clinical care, educational facilities, etc. To take care of the possibility that the rampant infection, particularly in the poorer urban areas given their haphazard growth and insanitary environments might break out in epidemic form, vaccinations, hospitals and selective measures for improving drinking water and sewage disposal have been resorted to. Otherwise the rural areas and the urban slums where most of the population lives, remain by and large untouched by the existing health system. For the health system to reach them in any significant way, within the functional approach, requires heavy doses of public expenditure. In the absence of effective preventive measures, the individual's own approach towards health care has been that of coping with repeated attacks of infectious diseases only through medical interventions. The private consumption expenditure on medical and health care as estimated from the 28th round of the NSS in 1973/74 was three times the public expenditure on this activity (Lakdawala, 1978)

Since effecting public health measures through environmental sanitation and provision of housing and safe drinking water is an expensive proposition, the Indian State, helped by advancing medical technology and international assistance, resorted to the easy alternative of tackling communicable diseases through vertical programmes that involved the use of known and tested technology such as vaccination and DDT spraying in the case of small pox and malaria respectively, and isolation and treatment as in the case of the other major communicable diseases such as TB and leprosy. With the exception of vaccination and revaccination against small pox, all the other known medical interventions presupposed the existence of effective public health measures and in a situation where the latter condition did not exist, could be expected to have only limited efficacy.

Next to small pox, the vertical programmes showed some signs of success in the case of malaria, supported through international aid for the import of powerful insecticides and drugs which had proved successful in malaria control in the second world war. Between 1953 when the National Malaria Control Programme started (it was stepped up to 'Eradication' in 1958) and 1965, the incidence of the disease was brought down from around 100 million cases and 1 million deaths to 1 million cases and no reported deaths (GoI, 1977.64 Table 51). These achievements as Cassen (1978:86) has argued, must surely be recognised as the single most important cause for the steep decline in in mortality that India has been able to effect after independence. The 1965 record, however, regressed soon after, and the incidence of malaria has been showing a sharp upward trend (GoI, 1977:64, Table 54). While the resurgence of malaria may not have affected mortality so far because of the dominance of the milder *vivax* malaria, it has grave consequences for the population

particularly since malaria tends to become chronic and debilitates its victims leaving them open to all other infections, and since malaria has been demonstrated to be a major cause of infant mortality. This regression in the case of malaria demonstrates the floundering of the functional approach. Apart from the 'human factor' — premature acceptance of success and complacency in sustaining the momentum of progress — and organisational problems, the main reasons for its failure structural in nature. They emphasise the need for coming to grips with the problems of disturbances in the ecology, centre state relationships, crisis in the economy and the general conditions for research and training. In the absence of planned research even while the eradication programme was in progress, full knowledge of the epidemiology of malaria and the ecology of the mosquito was lacking. Changes in the behaviour of vector and parasite partly due to developed resistance to insecticides and partly due to the disturbances in the ecosystem — in the form of population movements and congregation due to war, floods and large scale public works projects, clearing of forests for cultivation and refugee settlement and large scale use of insecticides in agricultural production, without an integrated approach to the environment — have contributed to the aggravation of malaria in the country (Ramasubban, 1978). The sluggishness on the part of the state governments to commit necessary funds of Malaria Eradication units, initially centrally sponsored and subsequently handed over to the states for the maintenance phase, represents the uneasiness in financial equations between the centre and the states. The shortage of insecticides for malaria control in the wake of the oil price rise and competition from the agricultural sector further highlights the interdependence of the communicable disease control programmes with the rest of the economy.

Epidemic cholera, which alone among the faecally related diseases has come under specific control measures — innoculation and chemotherapeutic measures — has been far more difficult to control, being food and water-borne rather than contagious and finding fertile ground in the widely prevailing unhygienic conditions of food and water use. The incidence of cholera which came down drastically from 176, 307 cases in 1950 to 22,065 in 1954 steadily rose to 66,076 in the following four years, came down briefly to 14,617 in 1959/60 but saw a sudden spurt again to the 1954-59 levels (GoI, 1977). Here, again, the effectiveness of the control measures was greatest in reducing mortality, and the deaths due to cholera which accounted for 2.4 per cent of all deaths towards the end of the colonial rule came down to 0.4 per cent by 1966/67 (Cassen, 1978). But given the absence of protected water supply and environmental sanitation, cholera continues to pose a threat of epidemic outbreaks during droughts, famines and floods.

The policy of vertical programmes for the control of communicable diseases also included TB, leprosy and filariasis. TB has remained more or less firmly entrenched since 1958 (Cassen, 1978 : 90) and nearly 2 per cent of the population is estimated to be suffering from TB, of which 25 per cent are infectious sputum positive cases (GoI, 1980 b). It is significant that in spite of a National Programme for domiciliary treatment launched in 1969, the total number of cases detected as a percentage of total estimated cases is only 30 per cent (GoI, 1980). Although several "operational lapses" were identified as reasons for failure in an assessment done by the Indian Council of Medical Research (ICMR, 1976) the more fundamental problems are those of poor nutrition and overcrowding. Moreover, the chemotherapeutic domiciliary treatment is still too long-drawn (18 months duration) for an average TB patient to sustain, given the long distances to be travelled to the health centres. The deceptive feeling of improvement in the first phase of treatment may also be responsible for discontinuation and relapse, in the absence of regular supervision (Cassen 1978). The growing evidence on the ineffectiveness of BCG in several cases and its temporary nature in providing immunity, points to the inevitability of taking cognisance of the structural factors. The National Leprosy Control Programme which was launched in 1955 has also not made any headway. More than half the population (GoI, 1974) is exposed to the risk of contracting this disease which flourishes under insanitary and overcrowded conditions. There are 3.2 million estimated cases of leprosy in the country of which 20 per cent are infectious and another 20 per cent suffer from various deformities. The total number of cases detected as a percentage of total estimated cases is 60 per cent while disease arrested cases is only 20 per cent, which goes to show that the Control Programme has not really been effective and there has to be a much more concerted effort in controlling this disease. Much the same picture holds for filariasis which came under a Control Programme in 1955.

The control of communicable diseases through vertical programmes poses difficulties because

these diseases have linkages with multiple factors and dealing with them requires socio-economic changes and a concerted action in the field of public health measures. Accomplishment of this task within the context of the health system would require greater expenditure on health by the central and state governments and/or effecting redistribution within the health system in favour of public health measures, and reorientation of health policy, backed by determination to act in that direction, to tilt the balance in favour of the rural areas. Here, again, the main challenge lies in resolving the contradictions giving rise to the dominance of curative services over preventive services, the urban-rural dichotomy and the lack of commitment on the part of the State to provide necessary funds in the health sector.

The Indian medical profession has a longstanding record of service, and in its development it would rank quite high in comparison with many developing countries and is recognised by the Indian population as efficacious and functional in combating disease.

Western medical education had its early origins in colonial policy, when the first medical colleges were set up in the mid-19th century. Right from their inception these colleges received a steady influx of Indians. Around the turn of the century when the bacteriological advances of late 19th century led to the increasing professionalisation of curative medicine in the west, simultaneous with the visible and rapid deterioration in India of the health conditions among the general population, the colonial authorities found it a cheaper alternative to respond to the incidence of disease through extension of medical education and encouraging medical practitioners (both European and Indian) rather than spend government resources on sanitary reforms for the general population. The medical professionals, however, remained concentrated mainly in the urban areas, which also meant constant contact with sources of power. The rural areas remained by and large ignored and left in the hands of the practitioners of the traditional systems of medicine.

The concentration of health services in the urban areas continues even thirty years after independence, and it is only very recently that we are witnessing an increase in the flow of practitioners in the western system of medicine to the rural areas. State action to provide health services to the rural population was initiated through a network of Primary Health Centres (PHCs). The PHCs, when set up, were not meant to remain curative centres. It was envisaged that an integrated preventive, promotive and curative structure could be built into the PHC system, and that this was just a matter of creating a team reflecting the three areas of work. The concern of the PHC, therefore, was meant to be mother and child welfare, control of communicable diseases, environmental sanitation, school health, basic health education, collection of vital statistics, immunisation and medical care services. Obviously too much was being expected from the PHCs and given the overall national bias towards curative and family planning services, the PHCs, too, in practice, soon turned into curative centres.

TRANSFERRING MEDICAL TECHNOLOGY
Reviving an Umbilical Connection?

meera chatterjee

The American Association of Physicians of Indian Origin and the Medical Council of India have recently agreed to sponsor a new scheme for training Indian doctors in the latest medical techniques. This article describes the elements of the scheme and discusses its implications especially in terms of its relevance to the Indian health scene and the dependency relationship it would reestablish and strengthen. The author contends that government has devised an ideal plan to keep an important restless and fairly politicised group — medical professionals — happy at only a small financial outlay. Could this money not be better spent on strengthening existing sources of medical knowledge such as professional foreign journals or available medical equipment? Or for that matter, could the money not be better spent on strengthening basic health care?

The scheme goes into operation sometime this year and needs urgent consideration. We invite readers to critically examine the scheme and to generate debate around the issues it raises in SHR and in other forums as well.

A new scheme to "transfer high technology" in the field of medicine has recently been announced by the Health Ministry. The Ministry has joined hands with the Medical Council of India (MCI) to support a venture of the American Association of Physicians of Indian Origin (AAPIO). We are told that this scheme was cleared "at the highest levels" last year, and will commence during the course of this year *(Statesman,* 1985*)*.

What is the proposed content and mode of functioning of the scheme? From the information available, it appears that Indian doctors residing in the USA will be invited by the Medical Council to train their local counterparts in the latest medical developments. Training will be "on the job", using demonstration techniques — "most probably" on patients. "New" medical technology is to be used. It is proposed to train doctors at 20 centres and in 20 different medical specialities in the next few years. Each group of trainers is expected to consist of 50 doctors. The first such group will travel to the major cities of Bombay, Delhi, Jaipur, Madras and Trivandrum by the end of this year. They will undertake training in urology, neurology, cardiology, etc., staying for "no more than three to seven days" at each centre. The cost of the scheme is intended to be borne by the individual doctors from the US— an estimated 100,000 dollars this year — except for their local transportation and stay costs which will be met by the Indian Government. The scheme is proposed on an "ongoing basis".

Several points need to be made about the proposed scheme and some questions raised alongside. First, one must note that the programme is geared towards the *training* of local specialists in the use of recently developed medical technologies rather than to the transfer of *manufacturing* know-how. It would be interesting to know specifically which medical technologies will receive attention, and whether the equipment involved is manufactured locally. The only clue we have is the emphasis placed on "new" technologies and "specialist" centres and personnel. This leads one to believe that the training might be in sophisticated medical techniques for which the equipment is not locally manufactured. In the absence of specific plans for the concurrent importation of blueprints to manufacture the equipment indigenously, one can only conclude that the government intends to import ready-made equipment from abroad for use by the trained specialists (or has already done so). Is it the government's intention to enter into schemes which provide a market in India for exogenously manufactured equipment? If this be the case, I must opine that the government should not be spending the very scarce resources of the health sector - however little of them - on such an objective.

A second question that must be raised is : Is the scheme a good way to bring local medical specialists up-to-date with the latest technological developments? To answer this question one can compare the circumstances in which the 'trainers' acquired their knowledge, and those in which they seek to impart it. The American medical practitioner practices his speciality in a milieu replete with the latest medical technology. The American doctor is inundated with information on the latest developments through literature, sales men, the media, access to professional associations and speciality conferences

(where, incidentally, a prominent part is usually played by the promoters of new drugs and equipment), not to mention his everyday work environment. On top of all this, according to a spokesman of the AAPIO, US-based doctors study their speciality an extra 50 hours a year to bring themselves abreast of the knowledge required to pass th ir licensing exams.

In contrast, the scheme proposes "three to seven hours" of demonstrations for the local doctors at specialist centres. The Indian medic, though also exposed to a fair amount of promotional literature from drug and equipment firms and some of the other 'aids', does not have an easy access to broad-based scientific literature which can assist him in making reliable judgements on the use of new materials. As a case in point one can cite the rapidity with which private practitioners prescribe the latest formulation of a drug. The culture of "kickbacks" from company salesmen (calendars, plastic knick-knacks, tickets to dinner at a local five-star, free samples, support for travel to conventions, and much more) has tended to subvert the spirit of scientific enquiry, and even clinical ethics. On the other hand, practitioners may hesitate to acquire even time-tested diagnostic equipment at their private clinics, largely because they have no shortage of clients, regardless how 'backward' the service they deliver. (None of this is to say that such abuses do not take place in the US as well, but the points of check-and-balance are considerably different.)

The situation of public medical personnel — including those at specialist centres — is similarly problematic. They work in intensely over-crowded and poorly supplied circumstances. There are severe bureaucratic and financial constraints to the acquisition of new equipments. Adjunct medical libraries are mostly in a sorry shape. Few professional associations bring out high quality journals, and personal subscriptions to foreign ones are prohibitive. There are few incentives or opportunities to upgrade one's knowledge and skills. Thus, the very different milieu of trainers and trainees will make the transfer of knowledge extremely difficult. *One might suggest, provocatively, that the 100,000 dollars the AAPIO proposese to spend annually on airfares to India would be better spent on supporting journal subscriptions for Indian institutions, or on schemes to provide young Registrars and Senior Residents who are anxious to upgrade their skills access to the "interesting"/difficult cases and specialist equipment which are usually nabbed by their seniors.* Such efforts to fertilise the soil before the specialist knowledge is transplanted may result in a richer harvest.

It is in this context that the fact that the proposed scheme does not mention the importation of any equipment or blueprints gains extra significance. "Three to seven hours" of demonstration will not overcome the problem of short supply of equipment extant at most centres. Does the government see this as a lesser constraint to the proper functioning of its health institutions than a lack of training in the "latest medical developments" of its doctors? Of course, much sophisticated medical equipment is already manufactured locally and therefore does not need to, indeed should not, be imported. But the heavy burden on specialist health centres, the lack of adequate procedures and facilities for maintenance and repair of equipment, the bureaucratic red-tape which delays or prevents the acquisition of replacements, as well as the politics and malpractices regarding the use of certain types of equipment at public health institutions remain major problems the government needs to tackle. The third point then is that, even assuming that the training programme is successful in transferring the requisite specialist knowledge, it is difficult to see how the specialists will be able to apply their training given existing conditions.

A fourth and related question is: Are the Indian doctors travelling home from the US the most suitable trainers for our local specialists? We must recall that most of these doctors would have left India after their early medical education, acquiring the bulk of their specialist expertise abroad. Notwithstanding their Indian origins and basic exposure to medical care in India, how appropriate is their practical expertise when transplanted from the sterile, almost martial, atmosphere of a US hospital or clinic, to a local centre where even the supply of gauze and cottonwool, leave alone adequately aseptic instruments and operation theatres, is in doubt? The main reason, however, to concede their suitability (assuming — only momentarily — that a training scheme is necessary or desirable) is that it is difficult to think of a better alternative. Non-Indians from the West have the same handicap, perhaps without the mitigating factor of cultural empathy. Sending local specialists abroad for training is of course a greater burden on the exchequer, and runs the risk both of irrelevance and of further 'brain drain' although this has worked in many instances in the past.

Returning to the proposed scheme, one is compelled to ask, who are the intended beneficiaries? In view of the very short training that will be given and the lack (to our knowledge) of concurrent plans to overcome the bottlenecks of inefficient management, poor logistics, highly politicised working conditions, and low pay that hamper the functioning even of our super-speciality centres, it is doubtful that the local specialist trainees have much to gain. The patients on whom the techniques would be demonstrated would merely be playing the roles of guinea pigs, the likelihood of a spread of benefits to vast numbers being most remote. Thus, one is forced to seek the answer to this fifth question elsewhere, for example, in the participating Association of Physicians or in the individual physician trainers themselves.

As the membership of the AAPIO currently numbers some 25,000, it is worth investigating whether the scheme passes muster on the ground that a sizeable group of important people would be benefited. Simple arithmetic, however, tells us that over the next 16 years (until the year 2000 by which time the world community is striving to achieve "Health for All"), at the current rate of 50 doctors per year, 800 may participate in the scheme. Alternatively, if one allows for a five per cent per annum rate of growth in numbers of participants in the scheme, the total may rise to 1200. Even this higher figure is less than five percent of the current membership of the AAPIO (which will inevitably increase over the years)—a figure so small that one would not expect sizeable benefits to accrue to the Association at large, especially as we have not been told of any mechanisms that the Association proposes to introduce to "spread" the effects of such a scheme among its members. We must remember too that the AAPIO is an umbrella organisation comprised of 15 other associations of Indian physicians resident in the US. The smaller organisations and their members are scattered throughout the country, a land two-and-a-half times the size of our own vast one. Doctors in the US also work under most rigourous, albeit better facilitated and more remunerative, circumstances. *So, how a 1000-odd fellows who have participated in training their counterparts for "three to seven days" on one occasion in India can benefit their own larger community remains to be disclosed.* How their participation in such a scheme can help to bring about the political clout that they aspire to within the American medical fraternity and with the US congress is certainly impossible to see.

In the absence of the possibility of wider fallout from this programme—either to the US-based or indigenous professions, one can only conclude that the main beneficiaries of the scheme would be the participating doctor trainers. To put this into perspective, it must be realised that many of these doctors moved away from the land of their birth and early medical training with feelings of despondency and in search of better opportunity. Thus, we need to consider their participation in the scheme at a purely human level. The scheme provides a mechanism through which they can make up in some small part what they have taken from their homeland and the government (and thereby "the Indian people") in the way of a highly-subsidised and western-oriented medical education. In my ten years of residence in the US, I knew many Indians including professionals in the health field, who felt intense feelings of guilt on this score, and constantly and earnestly searched for ways to assuage this guilt. Another feeling was that of confusion about cultural identity to which many emigres are subject and Indians in the US — doctots included — are no exception. This is manifest in a desire to have both worlds—the better-heeled, more efficient working and living environment of the west, as well as the more "homely", colourful, and meaningful life of India. Thus, the scheme at another level provides an opportunity to bring this dream to fruition. If nostalgia, aged parents, or the search for a prospective son-in-law (a doctor who will quality for a Green Card?) draw participants to the scheme, after the seven days of training will come the family reunion, the shopping spree, the trip to Kashmir. Given the groups of 50 or more, the scheme may be "development tourism" in its most disguised form yet.

In sum it is possible that the doctors of the AAPIO would benefit from this scheme, but as far as I can see the benefits would be social and psychological rather than professional.

Lest the reader misunderstand, let me be perfectly clear. Both the sets of feelings mentioned are perfectly human and one sympathises deeply with those who experience them. But the question here is: is it necessary or appropriate for the Indian government to use its money and materials supporting local transportation and stay costs, not to mention the valuable time of the trainees and the fanfare that will undoubtedly accompany the training, to assist a few individuals (who are fairly comfortably off) to overcome their pangs of conscience or estrangement? I think there are more pressing priorities for the very scarce resources of the health sector.

If the scheme fails the test of its overt intention — professional development — we must consider a sixth issue, its possible "hidden agenda". The first item on this agenda could be the conduct of collaborative research between the two groups of doctors. India, as we well know, provides a huge sea of human beings on which experiments could be conducted, a vast range of pathologies which pose real scientific problems or can be used as "models", and sufficient institutional facilities for highly sophisticated experimentation. Similar material is hard to come by in, say, a US situation while the medical-scientific community there faces immense pressures to do significant original research, "publish or perish". Many Indian practitioners also would welcome opportunities for collaborative research because they may have insufficient funds of their own, they may be devoid of ideas, or they may be facing a problem "getting published" in reputable international journals. These problems could be overcome through collaborative efforts. The scheme under discussion may well intend to foster such 'mutually beneficial' arrangements. As a young doctor friend of mine put it, "in 'three to seven days' there is little the US-based doctor can teach — but much he can learn" and, I would add, arrange.

On the face of it, such collaborative efforts should perhaps be welcomed if they further the cause of science. But the point at issue is whether this government appointed scheme will provide any safeguards against the abuses with which we are aware the system is already rife. While in the west, human experiments and trials are rigidly controlled by law, medical ethics review committees have been widely established (particularly in large hospitals affiliated with teaching or research institutions), and wronged patients or unknowing individuals have legal recourse through malpractice suits, in India the field is almost wide open. We have no laws expressly controlling human experiments, other than torts. The potential of medical technology to be misused in our social and economic context is amply illustrated by the saga of amniocentesis and fatal sex determination, and legal lacunae by the governments inability to bring unscrupulous medical practitioners to book in this case. Ethical guidelines issued by the Indian Council of Medical Research are at best applicable to its own institutions and projects, and not binding on others, nor on private practitioners. Although consent may be sought at hospitals and clinics for various invasive procedures, this is rarely "informed".

There is a second possible item on the scheme's hidden agenda. It may simply be another way of attracting investment from non-resident Indians Indian doctors in the US are certainly a group worth enticing as the most successful among them would have annual earnings of over 1 0,000, dollars and considerable savings. Their membership of associations makes them easy to reach with investment propaganda. The doctors also enjoy prestige among other non-resident Indians (NRIs), and so there could be some 'snowball effects' on investment. Without going into the pros and cons of NRI investment I should like to take a close look at whether the mechanics of this scheme would meet this objective and, more importantly, at what the side effects may be for the country's health system. Regarding the mechanics, I have already pointed out that the number of doctors the scheme can reach is small. Although we do not know yet what criteria would be used by the AAPIO to select participants in the programme, if a good proportion of them are to become investors, selection would have to favour those who are 'commercial-minded' and have large bank accounts. In the US, as in India, wealthier doctors tend to be in private practice rather than in public hospitals or academic institutions. They are likely to be the best participants in the scheme from the investment point of view. But they may not be the best candidates (even from among the members of the AAPIO) from a professional point of view, suggesting a diametral contradiction between the scheme's overt and possible covert aims.

There are also other possible negative "side effects". In the hope of attracting financial investment, are we potentially adding to the "brain drain" of doctors out of the country? We must not be blind to the continued desire of many Indian doctors to emigrate — and this scheme may provide a good opportunity for the 'recruitment' they seek. There is a growing disenchantment with emigration to Africa, the Middle East and the Gulf, and a renewed effort to get to the countries of the west is evident. There may also be signs of a relaxation in the embargoes placed by Western countries on immigration of South Asian doctors five or seven years ago when their health systems were saturated and when a sense of international responsibility in the wake of the Health-for-All movement may have prevailed. A demonstration that an emigrating doctor can have his cake and *roti* too may act unconsciously to motivate others to follow suit. Thus, while the scheme may meet its unspoken investment objective, it may obliquely harm the existing medical services. It is worth recalling the Hippocratic oath - and hoping that our policymakers and the doctors who propose

to participate in the scheme will do the same: "First, do no harm".

As an aside, it is possible of course that this scheme is seen (at the same time as being investment-motivating) to be precisely an answer to the brain drain issue. By making specialist training available locally, it may be hoped that the desire of young doctors to go abroad, ostensibly in search of such training, would diminish. *It is also easy to see that by putting out a relativaly small amount of funds, the government has devised a 'plum' to keep an important, restless, and fairly politicised group of professionals — medical specialists — happy and feeling that India will enter the 21st medical century on time.* Neither of these situations is likely to obtain, however, in the continued presence of the irritants discussed earlier, which motivate both the outmigration phenomenon as well as the political volatility of young doctors.

Another possibility that deserves some consideration is that the scheme has some actual or potential connection with the programme of concessions to attract non-resident Indian professionals to return to India — to reverse the brain drain, as it were. All that needs to be said on this, in the light of the foregoing discussion, is that concessional strategies tend to gloss over the underlying causes of the exodus. Thus, in lieu of them — if there is any connection — the government would do better to concentrate its attention on improving the working conditions of those doctors who remain in India, preventing not just legally but substantively, a further drain.

Returning to the investment possibility, one can further refine it. The government perhaps hopes that the US-based doctors will invest not just generally in Indian enterprises, but specifically in the medical and health sector. It may be with such prescience that the vice-president of the AAPIO has expressed confidence "that this Scheme will do a lot of good to the cause of the Indian medical services" (for, as we have suggested, it is unlikely that the training itself will achieve this broadside.) The dual health economy is well-ensconced in India. Many large hospitals and specialist treatment centres have been established by private investors including major industrial houses such as the Mafatlal and Modi groups. Privatisation is also being seen as the future mode. The recently-framed National Health Policy specifically calls for the encouragement of private investment in speciality and super-speciality services, as well as for the government to "utilise and assist" private voluntary organisations to participate in health services. At one level, these are welcome suggestions because of the innovation likely to be brought to the health sector through these mechanisms, and more so because they are intended to reduce government expenditures for sophisticated medical care, thereby making more monies available for primary health care and public health services. The proposed scheme may be seen as a step in this direction, but there is also the grave possibility that the cart has been put in front of the horse. There is already considerable investment in specialist health facilities in terms of their share of the health pie. What is needed, first, for "health for all" is a reallocation of funds (at least **plan** funds) to rural health schemes. It is also essential to enlarge the total allocation to health. To put further investment into the sophisticated medical sector (however small the amount) without such reallocation is to relegate much of the National Health Policy to the status of a lame duck. If the budget to the health sector does not increase, both in real terms and in terms of per cent of GNP, such skewed investment may be tantamount to the government opting out of health for all altogether. To attempt to attract external investment through a scheme "update" specialised medical personnel in the "latest developments in medical science" is to give the lame duck a further kick in the pants.

This brings us the most crucial question of all : is the proposed scheme relevant at all to the country's needs? The National Health Policy itself has called the existing system of sophisticated health services "inappropriate and irrelevant" to the country's needs. Is a scheme which proposes to upgrade them any less so? The specialities mentioned thus far are certainly not those required to treat the major diseases or prevent the untimely deaths in our country. In this respect, the scheme is what Lewis Thomas has called "halfway" technology rather than "real high technology" which is addressed to significant problems, is effective, inexpensive and inconspicuous. In the latter category are many potential points of collaboration between the government and the AAPIO.

If the government is at all serious about its commitment to primary health care, it should perhaps encourage the AAPIO to 'invest' in establishing clinics to supply basic health care and medicines to the remotest rural areas, and to "donate" personnel time to training trainers

of village health workers. But note : any collaborative venture or technology-transfer must resist the malproportions of one of Mr Raj Narain's efforts to provide medical services to rural areas. If the import of the 300-odd over-sized mobile medical vans has come to be known as the "white elephant scheme", any encore deserves worse epithets. If the absorption of such donations into the public rural health sector presents problems, there are innumerable private, community-based health programmes which would do good work with them. Thus, the two aforementioned aims of the Health Policy might be collapsed into one more in keeping with its overall intention — private collaborative enterprise for rural health care. However, I broach this idea with caution because, of course, the countryside is also dotted with agencies who wouldn't do any work at all, there are many examples of foreign donations being frittered away, and I know of atleast one major unhappy experience of an NRI-supported rural "enterpreneurship' programme going awry. The point here is simply that the challenge lies in rural health, and that a programme of greater benefit to more people than the proposed one might be designed around this challenge. Even the small funds envisioned to be spent on this scheme could be used to establish basic health care, so that by the end of the century a few more of our countrymen and women and children might be closer to the dream that is "health for all". As it is currently conceived, the proposed scheme may reestablish an umbilical connection, but the product is likely to be stillborn.

BHOPAL NEEDS YOU

In March the Medico Friend Circle — a group of doctors and health workers — undertook a systematic study of the affected population in Bhopal. In the coming months they will publish the report of the study and plan to disseminate the information mainly to the local population, to doctors and to the health establishment and to voluntary groups and activists working in and on Bhopal. Follow-up plans also include a study of pregnancy outcome since the disaster.

MFC appeals for your support, donations and involvement all of which are urgently needed. Cheques may be sent in favour of MFC Bhopal Fund. For further information contact : Dr. Ravi Narayan, 326 V, Main, I Black Koramangala, Bangalore 560 034.

Some Good News on the Drug front at last !

Ciba Geigy has withdrawn clioquinol containing and related drugs from March 31, 1985. This group of hydroxyquinolines have been proven responsible for a serious nerve disease SMON (subacute myelo-optic neuropathy). The drugs withdrawn are Mexaform, Entobex and Enterovioform.

MONOPOLY CAPITAL AND THE REORGANISATION OF THE HEALTH SECTOR

j warren salmon

The 'health care crisis' proclaimed by Richard Nixon in 1971 revealed the health sector's interconnections with the overall political economy. These extend simultaneously to problems in the health status of the people; the effectiveness of medicine itself, and the organisation and financing of medical care services. The ruling class has attempted to resolve the present crisis by introducing a structural reorganisation of the health sector. The corporate class has become increasingly active in health policy and programme development at national as well as local levels. This article, reproduced from 'Review of Radical Political Economy' briefly looks at the role of monopoly capital in this reorganisation. What is the capitalist perspective on the crisis in health care ? How are they advancing their class interests by themselves and through the state for a redesigned health care delivery system? The author reviews the discussions, activities and important publications of a few selected capitalist planning bodies, showing their ideological development as they educate the corporate class. These discussions are a key to shaping a class stand to eventually transform health services delivery under monopoly control.

"There is a better way to go and that would be to strip the medical societies of the power to inhibit more efficient methods of delivering medical care — corporate organisation, for example — and the various restrictions on competition."

Editorial, *Wall Street Journal*
January 16, 1976

The present organisation of the health sector, with its excessive use of resources, has come into contradiction with the needs of monopoly capitalism today. A petty-bourgeois mode of health services (structured around solo fee-for-service medical practice and cost-reimbursed hospital care) will yield over the next few decades to a new, qualitatively different stage of development[1]. This emerging delivery system may eventually be dominated by Health Maintenance Organisations (prepaid group medical practices) sponsored by large corporations financed by some form of national health insurance, and regulated by corporate-controlled planning bodies.[2]

Monopoly capital recognizes the health services industry as organisationally backward compared to other sectors of the economy. Although several modes of production coexist, a small scale mode still predominates, principally controlled by petty-bourgeois physicians. This condition entails institutionalised waste, including low productivity of the health labor force, substantial clinically unnecessary care (and its related high hospital utilisation), and the allocation of substantial resources to non-productive segments of the population (e. g., the poor, disabled, aged). From the monopoly capitalist perspective, the health sector diverts a substantial portion of state funds and an increasing amount of variable capital costs (in the form of fringe benefits) from the sphere of monopoly capital. The surplus generated in the delivery of medical care is chiefly appropriated by physicians, hospitals, medical schools, and nursing homes[3].

These conditions contribute to escalating and yet-to-be controlled costs,[4] under the present organisational form and control. There are two aspects of this cost problem.

1) 118.5 billion dollars were spent for health services in 1975, more than a 200 percent rise since 1965. Health expenditures are thus rising more rapidly than the overall rate of inflation in the economy, propelling them to 8.3 percent of the GNP last year.

2) 57.9 billion dollars were spent by government — 42.2 percent of these total expenditures — and is critical in light of the fiscal crisis of the state.[5]

Over the past decade the federal and state governments have instituted increasing cost controls; however, the cumulative effect of these policies has been minimal.[6]

This problem of escalating costs is related to an additional one concerning doubts about the general effectiveness of medical care services in ameliorating disease patterns related to heart, cancer and stroke. The leading mortality indicators for Americans under 45 — accidents, suicide and homicide — are conditions which the medical care system does not, and cannot, address, given its present form.[7] Studies are showing that health levels are not altered significantly now by incremental medical care services[8]. A growing ideological

response may shift attention away from medical care institutions to contain the costs of the health sector."

The drastic decline of U.S. power in the world capitalist system has shaped an international situation which has aggravated the acute domestic stagnation. To cope with these conditions, the capitalist class has been looking more and more at the potential of the health services industry for greater social efficiency. In the present economic crisis, the containment of social consumption expenses can provide funds for private investment in the production sectors. Health policy has been encouraging attempts at general rationalization (cost cutting, profit maximization, forcing higher productivity).

At the same time, various segments of capital are responding to opportunities for greater profits to be derived from both the production of health services[10] and the circulation of commodities through the health sector (e.g. drugs, hospital equipment and supply, construction, systems and communications, legal, accounting and management services, etc).[11] As industrialisation proceeds in the health sector (mass production, elaboration of the division of labour, greater capital intensification, bureaucratisation, etc.), these industries will seek greater capital flows toward the sector.

Renaud has demonstrated how capitalist growth, while giving rise to disease patterns in society, also institutionalises "solutions" to disease which are compatible with capitalism, in the form of a commodification of health services.[12] With alienation and disease creating a greater dependency by the working class on health (and other human) services, these services must function more and more as mechanisms for social control.[13] However, the present structure of health care delivery has not developed sufficiently for monopoly capitalism today. A new organisational form is required, and it will arise under conditions similar to those other sectors where petty-bourgeois or pre-capitalist forms historically were smashed or co-opted.[14]

It is surely not new for capitalists to be actively restructuring the health sector. Berliner has detailed how the Carnegie and Rockefeller Foundations in the beginning of the century virtually rebuilt the entire medical care system by endowing research institutes and selected medical schools.[15] This intervention strongly influenced the rise of the presently-dominant organizational form in the health sector, which has served through to the present period.

Stagnation and crises necessitate a growing awareness of monopoly capital's common interests (as well as its conflicts). The coming together of major capital segments to discuss and formulate general policies in itself yields a greater measure of class consciousness.[16] Policy-planning organisations, (such as the Trilateral Commission, Business Council, Comittee for Economic Development, Business Roundtable, etc.) have lately become the arenas for working out programs for the capitalist class as a whole. Their activities provide a system of cooperative interpersonal and interorganisational relationships based upon a commonly-held class perspective. The role of these "consensus-seeking" groups becomes critical, with the mounting contradictions of advanced capitalism and the crescendo of challenges to the American capitalist system on both the international and domestic levels.[17]

Today the "class-conscious corporate directorate"[18] is speaking directly to monopoly capital's needs from the health sector in a number of important publications and conferences. The following sections will review a few of the activities of selected planning bodies, showing their ideological development as they educate the corporate class. As yet, no definitive analysis on the nature and function of the health sector has developed, nor has a comprehensive strategy for the capitalist class as a whole emerged. Nevertheless, a class stand is shaping as the problems for monopoly capital are detailed and potential solutions are discussed.

In contrast to the last decade, *Fortune*, *Forbes*, *Business Week* and the *Wall Street Journal* have been devoting major amounts of space to health care problems and editorializing for a changed structure to favor capitalist interests.[22] The *National Journal* provides frequent indepth analyses of health care issues to apprise business leaders of legislative developments. All of this interest by the business press (coupled with the popular media's attention to health and health care inadequacies)[19] is a marked escalation over their coverage prior to 1970 — a change which parallels the new interest by capitalist planning bodies

Committee for Economic Development

The Committee for Economic Development (CED) is one of the central educational and policy-making organisations of the corporate class; Domhoff calls it the "major spokesman for the

business viewpoint." Highly influential in state policy formulation, it addresses their societal concerns in lengthy policy statements.[20] It represents a more "progressive" capitalist perspective (generally the longer view of reshaping society) and produces studies that are somewhat broader and less detailed than the issues analysed by the liberal Brookings Institution[21] or the right-wing American Enterprise Institute for Public Policy Research (AEI).[22]

The CED provided a beginning outline of their design for the health sector in a report entitled *Building a National Health Care System* in April 1973. It recommended health maintenance organisations (both profit-making and nonprofit) for restructuring the delivery system. A health maintenance organisation brings together a comprehensive range of medical services into a single organisation, providing services in a benefit package for a fixed contract fee which is paid in advance. A proposal was made for health care providers to be financed through prospective budgeting, with fees and charges fixed in advance. A national health insurance program, providing a basic level of health benefits for all Americans, would be administered by a National Health Insurance Advisory Board. This basic benefit package for *all* Americans, of course, would be a phased and "practical program that does not raise false hopes by promising services that cannot be made available and does not lead to unwarranted increases in costs with little benefit to people."[23] Three categories of financing would be established: 1) employer-based insurance would be phased in for all workers and their dependents; 2) Medicare would be retained for the aged and disabled, 3) care for the poor, nearpoor, unemployed, and others would be provided through federally-sponsored community trusteeships. The policy statement further recommended a control and planning mechanism — which has now been enacted in Public Law 93-641, The National Health Planning and Resources Development Act of 1974.

In short the statement by the Committee for Economic Development essentially endorsed the health policy of the Nixon Administration and countered most of the stands taken by the American Medical Association, which has fought all attempts at restructuring and cost control.

The Business Roundtable

Perhaps the major capitalist lobbying group on health care has become the Business Roundtable (BR) and its associated Washington Business Group on Health. Made up of the chief executive officers of the 160 largest corporations, BR was formed in the early 1970's to develop class discussions and to formulate corporate policy on labor problems.

In June 1974 the Business Roundtable convened a conference on health care legislation to build a consensus among chief executive officers about what business should be getting from the health sector. In an opening address, the chairman of Eli Lilly Company, the drug manufacturer, noted that "at a recent meeting of the Business Roundtable there was complete agreement that the importance of the health issue to every company should have a very high priority as an issue in future months towards which we should devote our continued and dedicated attention."[24] The panel of speakers was impressive. Chairman of the Business Roundtable's Subcommittee on Health Policy; Chairman of the CED Health Policy Committee; former Congressman William Roy; who authored the Health Maintenace Organisation Act of 1973; a representative from the office of the HEW Assistant Secretary for Health and Scientific Affairs; and Russell Long, Senate Finance Committee Chairman and sponsor of a health insurance bill. While endorsement was encouraged for Senator Paul Fannin's National Health Standards Act (the national health insurance bill of the Chamber of Commerce), what seemed to be emerging was a firm conviction that restructuring the delivery system was a necessity before legislation on the national financing of health care. In the midst of the recession, coupled with the state's fiscal problems, capital was displaying its fear of increased labor costs.

The Conference Board

The Conference Board based in New York City, is a research organisation concerned with "business economics and business management." Its numerous studies address problems of the firm, which it then relates in its published findings to social policy issues. Their message promotes the common interest of capital in the "efficient operation and sound development of voluntary productive enterprise."

The CB conducted several extensive studies on health care funded by the U.S. Department of Health, Education and Welfare and a consortium of large corporations and foundations. *Top Executives View Health Care Issues* (1972), the first product of this broad CB study in health, surveyed 118 executives about: 1) the nature of the nation's major health problems, the need for new legislation to deal with them, and the particular pending

legislation; 2) the ways in which health costs to business might best be controlled; 3) the desirability of companies creating or expanding their own in-house medical services; 4) a strong business role in community efforts at health services planning, controlling hospital and other health costs, and developing prepaid group practice plans and other new health delivery forms; 5) potential changes over the next decade in corporate health care activities; and 6) the order or priority that business should assign to health care relative to other social issues (e.g. environment, product safety, minority employment and urban redevelopment).

A subsequent study on *Industry Roles in Health Care* surveyed eight hundred large firms to provide a statistical examination of present corporate health care programs. The narrative description of these programs and the suggestions on the "appropriate management response" to the health sector delineate specific policies and activities of corporations in restructuring health care delivery arrangements for their workers and surrounding communities.

Another publication, *National Health Insurance and Corporate Benefit Plans* grew out of two surveys on corporate health programs (a separate one on executive health), which secured the cooperation of 1800 companies for their extensive detail. The national health insurance bills before Congress were analyzed for their effect on industry benefit plans, along with an assessment of labor union attitudes and actions. The report concluded that "a substantive intervention by the Federal Government would have a major impact on the benefit planning, cost sharing, and bargaining, but little direct effect on the benefit coverages to be provided to workers. Benefits to low-wage workers and unemployed would increase greatly "[26]

These reports provided a foundation to the forward and sophisticated thinking presented by the speakers in a CB-sponsored *Health Care Issues for Industry* Conference in April 1974. Over 200 corporate executives and health and government representatives met to discuss the "heavy health-related costs in the form of taxes, employee benefits, workmen's compensation, absenteeism, impaired productivity, and business stake in the allocation of the nation's resources and the health of its economy."[27] Walter Hamilton, former Deputy Assistant Secretary of Commerce under the Nixon Administration and now a CB Vice President, began the conference by observing that health care is "an industry whose methods and structures the business community has both the right and the obligation to study and seek to improve."[28] Dr. Paul M Ellwood, Jr., the chief architect of the Nixon Administration's Health Maintenance Organization Strategy, decried the lack of capitalist leadership in designing national health policy and suggested that:

". . free enterprise solutions that have been effective in solving the problems of conventional business can be applied with similar effect within the health industry, and that you are in the position to apply them. In other words, I am suggesting that you take certain active steps to make the health care market work, by encouraging HMOs to compete with the present system on the basis of prices and benefits."[29]

Dr. G.H. Collings, Medical Director of New York Telephone Company, urged corporations to become the "health care manager" for workers through their industrial medicine departments. An executive of Kaiser-Permanente, the largest HMO in the country with over two million subscribers, presented information on a cost-benefit analysis of occupational health measures to aid companies. A corporate officer from Motorola discussed his company's conflicts with hospitals in Phoenix, Arizona and Motorola's attempts in the community to contain their costs. A vicepresident of General Mills spoke of the corporate-sponsored HMO effort being designed and implemented in the Twin Cities area. Equitable, Prudential, Honeywell, General Mills, 3M, Pillsbury, and Mutual of New York are among the twenty corporations there reporting attempts to centralize health services into health maintenance organizations. With the information on the nature and extent of corporate involvement in health care activities from this conference and the CB studies, monopoly capital has positioned itself to initiate a more class-conscious analysis of the health sector and its relation to capital accumulation.

The Health Manitenance Organisation Strategy

Active state intervention to restructure the health sector was taking place amidst these conferences and publications by capitalist planning bodies and the upsurge in volume of health articles in the business press. The HMO strategy initiated by the Nixon Administration in 1970 had created an awareness among monopoly capital firms of investment possibilities in health care delivery. It was designed for "using the forces of the private sector" to "modify the entire system of health care."[30] Dr.

business viewpoint." Highly influential in state policy formulation, it addresses their societal concerns in lengthy policy statements.[20] It represents a more "progressive" capitalist perspective (generally the longer view of reshaping society) and produces studies that are somewhat broader and less detailed than the issues analysed by the liberal Brookings Institution[21] or the right-wing American Enterprise Institute for Public Policy Research (AEI).[22]

The CED provided a beginning outline of their design for the health sector in a report entitled *Building a National Health Care System* in April 1973. With the information on the nature and extent of corporate involvement in health care activities from this conference and the CB studies, monopoly capital has positioned itself to initiate a more class-conscious analysis of the health sector and its relation to capital accumulation.

The Health Manitenance Organisation Strategy

Active state intervention to restructure the health sector was taking place amidst these conferences and publications by capitalist planning bodies and the upsurge in volume of health articles in the business press. The HMO strategy initiated by the Nixon Administration in 1970 had created an awareness among monopoly capital firms of investment possibilities in health care delivery. It was designed for "using the forces of the private sector" to "modify the entire system of health care."[30] Dr.

Paul Ellwood[31] of *Interstudy*, a health policy think-tank, has consulted extensively with large corporations urging them to establish profit-making HMOs, converting their industrial medical departments into HMOs in order to "realize a susbstantial savings over present health expenditures for employee health care benefits.."[32] Through changing the present "sickness-oriented, piece-work basis" of the delivery system, the HMO creates a profit motive "to concentrate on keeping people healthy" and provide "greater efficiency."[33] HMO patients have a markedly lower rate of hospital admissions and a shorter length of stay than those covered by indemnity insurance plans of Blue Cross and the commercial insurance companies. According to Ellwood, HMOs would strengthen the role of competition by introducing economic incentives, and minimize the need for regulation by relying upon market mechanisms. Ellwood's dream of a revamped delivery system envisioned approximately 1000 HMOs across the country, organized similarly to large corporations (possibly as their subsidiaries) to serve up to serveral million persons each. One of his latest suggestions, as an ideological entrepreneur on health for the capitalist class, urges federal government subsidies (up to one million per year) for the nation-wide expansion of the "superclinics" (e.g. Mayo, Cleveland, Palo Alto, Marshfield, Geisinger, etc) as models for a national network of HMOs.[34] The state's role in this redesign of the delivery system would enhance monopolization and assure a rationalized organizational form.

To stimulate corporate-controlled HMOs, HEW under the Nixon Administration designed a program to attract funds from venture capital and investment banking firms, commercial insurance companies, and banks. Capitalist interest in HMO operations, both as commercial ventures and as a more efficient organization of present health care providers, rose as they understood how HMOs could control the runaway costs of the health sector and contain their labour costs.[35] A list of corporations who have been involved in HMO activity reads like the Fortune 500: Westinghouse, Texas Instruments, Sun Oil, North American Rockwell, Zenith, General Foods, DuPont, IBM, Kodak, Xerox, Upjohn, Mobil Oil, Standard Oil of Indiana, and a few dozen others. However, tight money over the past few years and the lack of substantial financing of the Health Maintenance Organization Act of 1973 (P.L. 93-222) by the Ford Administration have temporarily slowed this whole development.

Both profit and non-profit HMO plans have continued to expand, having doubled their enrollment (to approximately 8 million persons) over the past three years in 178 HMOs across the country.[36] However, new HMO projects are dependent on corporate and union support in their "marketing" activity (i.e., acquiring enrollees) to ensure their existence and growth. With the economy on the upswing and several problems resolved in the new HMO law, corporations may reinstitute their involvement in HMO activities and follow the example of R.J. Reynolds, which this year established its own HMO for its workers.[37] The National Association of Employers for HMOs, based in Minneapolis, was just formed this year by several corporations to guide firms in their HMO development.

Occupational Medicine Developments

While monopoly capital's investment in HMOs has not reached levels predicted by the Nixon Administration, corporate medical directors and employee benefits managers nevertheless have been developing mechanisms within their firms to eventually integrate industrial medicine and occupational health programs with the medical care of workers' families. Writing in a special issue on HMOs of the *Journal of Occupational Medicine*, one corporate medical director evoked the view that: "the scope of proper concern of the occupational physician has expanded quite far beyond his involvement with occupational injuries and disease. It now extends to the non-occupational health problems of the worker and his dependents, and the ways in which the health services they require are organized, delivered, and paid for."[38]

Another corporate medical director has said, in a speech entitled "The Balance Sheet in Employee Health Conservation," that the industrial physician may become the primary care physician of the future for the worker and the family.[39] William Jend, Jr., Medical Director of Michigan Bell Telephone Company, has argued that the "workplace is probabiy the ideal locale to practice real preventive medicine on a wide and effective scale."[40]

This ideological thrust,[41] coupled with actual program formulation,[42] by industrial medicine physicians, represents a slow but deliberate shift which may lead to a personnel system in which the firm will be able to provide health maintenance services to assure the productivity of the individual worker. This implies a profound change in

the content and control of medicine from that practiced today.[43]

In a larger context, the employer as "health care manager" will deal with worker alienation and disease, contain laborpower reproductive costs, and promote greater social control in an attempt to reduce the level of absenteeism and disability, turnover rates, wildcat strikes, sabotage, and poor quality products. The development of workplace medicine is one more step in the transfer of health services delivery to eventual monopoly capital control.

Directions and Contradictions

While these conditions are shaped and shape themselves from the outside, rapid change is concurrently happening within the health sector. Concentration and centralization in the production of medical care services have been rearranging patterns of control in the financing and delivery of care. Health industry groups such as the American Hospital Association, Group Health Association of America and Blue Cross are becoming more closely aligned with monopoly capital. Stimulated by increased efforts for bureaucratization and the application of managerial economics, the industrialization process in the health sector is bringing forth fundamental changes in its social relations of production. Meanwhile, regional planning efforts by health systems agencies and the forthcoming passage of some form of national health insurance may help create material conditions for further monopolization and a greater capitalist invasion.

As the rationalization of health services occurs during the present period of economic crisis, monopoly capital's class stand on health policy is being developed. Discussions have been centering around containing cost inflation in health care, redirecting medical dollar flows through the monopoly sphere, and eventual consolidation of health services delivery by large corporations. Recognition of their interest in more rational and precise social investment may lead monopoly capital to mold an organizational reflection of their need for human capital maintenance.

As the larger crisis of accumulation is addressed, the outlook of monopoly capital is becoming more highly developed. How capital can assure stability and predictability in the international and domestic situations is certainly receiving more and more class attention and action. It is crucial for us to analytically grasp this beginning ruling class coordination in the health sector also.

6. The federal government has adopted cost containment measures through the economic stabilization program: utilization review of hospitalizations under Medicare insurance for the aged and Medicaid for the poor; monitoring hospital admissions and length of stay by Professional Standards Review Organization, federally-mandated organizations set up by county medical societies; and authorities for planning construction and equipment purchases given to new regional health systems agencies. Futher, state governments have regulated commercial and non-profit insurance firms, and enacted certificate-of-need legislation for hospital and nurs-

Paul Ellwood[31] of *Interstudy*, a health policy think-tank, has consulted extensively with large corporations urging them to establish profit-making HMOs, converting their industrial medical departments into HMOs in order to "realize a susbstantial savings over present health expenditures for employee health care benefits.."[32] Through changing the present "sickness-oriented, piece-work basis" of the delivery system, the HMO creates a profit motive "to concentrate on keeping people healthy" and provide "greater efficiency."[33] HMO patients have a markedly lower rate of hospital admissions and a shorter length of stay than those covered by indemnity insurance plans of Blue Cross and the commercial insurance companies. According to Ellwood, HMOs would strengthen the role of competition by introducing economic incentives, and minimize the need for regulation by relying upon market mechanisms. Ellwood's dream of a revamped delivery system envisioned approximately 1000 HMOs across the country, organized similarly to large corporations (possibly as their subsidiaries) to serve up to serveral million persons each. One of his latest suggestions, as an ideological entrepreneur on health for the capitalist class, urges federal government subsidies (up to one million per year) for the nation-wide expansion of the "superclinics" (e.g. Mayo, Cleveland, Palo Alto, Marshfield, Geisinger, etc) as models for a national network of HMOs.[34] The state's role in this redesign of the delivery system would enhance monopolization and assure a rationalized organizational form.

To stimulate corporate-controlled HMOs, HEW under the Nixon Administration designed a program to attract funds from venture capital and investment banking firms, commercial insurance companies, and banks. Capitalist interest in HMO operations, both as commercial ventures and as a more efficient organization of present health care providers, rose as they understood how HMOs could control the runaway costs of the health sector and contain their labour costs.[35] A list of corporations who have been involved in HMO activity reads like the Fortune 500: Westinghouse, Texas Instruments, Sun Oil, North American Rockwell, Zenith, General Foods, DuPont, IBM, Kodak, Xerox, Upjohn, Mobil Oil, Standard Oil of Indiana, and a few dozen others. However, tight money over the past few years and the lack of substantial financing of the Health Maintenance Organization Act of 1973 (P.L. 93-222) by the Ford Administration have temporarily slowed this whole development.

Both profit and non-profit HMO plans have continued to expand, having doubled their enrollment (to approximately 8 million persons) over the past three years in 178 HMOs across the country.[36] However, new HMO projects are dependent on corporate and union support in their "marketing" activity (i. e., acquiring enrollees) to ensure their existence and growth. With the economy on the upswing and several problems resolved in the new HMO law, corporations may reinstitute their involvement in HMO activities and follow the example of R.J. Reynolds, which this year established its own HMO for its workers.[37] The National Association of Employers for HMOs, based in Minneapolis, was just formed this year by several corporations to guide firms in their HMO development.

Occupational Medicine Developments

While monopoly capital's investment in HMOs has not reached levels predicted by the Nixon Administration, corporate medical directors and employee benefits managers nevertheless have been developing mechanisms within their firms to eventually integrate industrial medicine and occupational health programs with the medical care of workers' families. Writing in a special issue on HMOs of the *Journal of Occupational Medicine*, one corporate medical director evoked the view that: "the scope of proper concern of the occupational physician has expanded quite far beyond his involvement with occupational injuries and disease. It now extends to the non-occupational health problems of the worker and his dependents, and the ways in which the health services they require are organized, delivered, and paid for."[38]

Another corporate medical director has said, in a speech entitled "The Balance Sheet in Employee Health Conservation," that the industrial physician may become the primary care physician of the future for the worker and the family.[39] William Jend, Jr., Medical Director of Michigan Bell Telephone Company, has argued that the "workplace is probably the ideal locale to practice real preventive medicine on a wide and effective scale."[40]

This ideological thrust,[41] coupled with actual program formulation,[42] by industrial medicine physicians, represents a slow but deliberate shift which may lead to a personnel system in which the firm will be able to provide health maintenance services to assure the productivity of the individual worker. This implies a profound change in

the content and control of medicine from that practiced today.[43]

In a larger context, the employer as "health care manager" will deal with worker alienation and disease, contain laborpower reproductive costs, and promote greater social control in an attempt to reduce the level of absenteeism and disability, turnover rates, wildcat strikes, sabotage, and poor quality products. ILLS OF THE HEALTH INDUSTRY

ravi duggal

"Corporate Crime in the Pharmaceutical Industry" By John Braithwaite Routledge & Kegan Paul, London 1984, £ 25.00

Illicit drug networks, contraband smuggling and terrorist gangs constitute popular international crime syndicates against which most countries have evolved elaborate and sophisticated means of counter. Transnational Corporations (TNCs) also operate an equally organised crime syndicate but to which invariably the states' regulatory and enforcement machinery look the other way or are deliberately kept as inadequate.

Pharmaceutical TNCs are probably the worst of their kind. The pharmaceutical industry forms the nucleus of the health industry. It determines the nature of the health industry and controls the latter completely. Pharmaceutical firms play a central role in health (as well as general) policy making and planning, education of doctors and other health personnel, and of course socialisation of consumers into a ' pill-popping" culture.

Pharmaceutical business is essentially transnational and therefore, its crimes acquire an even more serious concern, especially because there is a gross inadequacy of protection against the ills of the health industry. For instance even in the USA, where the consumer movement is probably the strongest in the world, marketing a drug with dangerous side effects is not even an offence unless the product is actually banned or there has been criminal negligence.

Dr. John Braithwaite in *Corporate Crime in the Pharmaceutical Industry* cites innumerable cases revealing that the transnational pharmaceutical industry has a worse record of international bribery and corruption than any other industry, a history of fraud in the safety testing of drugs, a disturbing record of criminal negligence in the unsafe manufacture of drugs, of unethical practices in pushing drug sales including smuggling and of global law evasion and financial fiddling whose worst victims are third world countries.

Unlike the times and crimes of Hitler, the brutalities of today's leading pharmaceutical corporations have yet to find a prominent place in world history. Many authors have documented in horrifying details the brutalities of the drug TNCs that have built up an industrial empire through inhuman criminal undertakings.

For example, Germany's I. G. Farben (today divided into Hoechst, BASF and Bayer) which operated a massive chemical plant at Auschwitz with slave labour of 300,000 concentration camp workers, tested drugs on a large number of workers who died in the drug-testing programme. The following extract from letters written to the camp at Auschwitz by I. G. Farben indicates the grave nature of the criminal offences indulged in by the pharmaceutical companies to multiply their profits :

"In contemplation of experiments with a new soporofic drug, we would appreciate your procuring for us a number of women . . . - we received your answer but consider the price of 200 marks a woman excessive. We propose to pay not more than 170 marks a head. If agreeable we will take possession of the women. We need approximately 150 . . . . . Received the order of 150 women. Despite their emaciated condition, they were found satisfactory. We shall keep you posted on developments concerning this experiment . . . . The tests were made. All subjects died. We shall contact you shortly on the subject of a new load."

Today Hoechst and Bayer are the largest and third largest drug companies in the world. They made capital through incriminating means; they were criminals and twelve of their top executives were sentenced to terms of imprisonment, for slavery and mistreatment offences at the Nuremberg war crime trials. (It must be noted, not for corporate crimes in which allied forces were equally involved). But once allied control loosened two of the criminals, Friedrich Jaehne and Fitz ter Meer, were appointed chairmen of Hoechst and Bayer, respectively.

Braithwaite introduces his book on Corporate Crime with this horror story and subsequently moves on to expose the various areas and mechanics of crime in the pharmaceutical industry with interesting but emotionally disturbing case-studies.

The Pharmaceutic Global Empire

The foundation for the transnational nature of the drug industry was laid sometime at the turn of

the century but only consolidating itself in the inter-war period. The modus operandi was invariably international traffic in illicit drugs. Bayer, at the turn of the century, used the same mass marketting tactics for heroin as it uses for aspirin or Baygon, the cockroach killer. Bayer even promoted heroin as a panacea for infant respiratory ailments ! Parke Davis similarly promoted with great enthusiasm the therapeutic virtues of cocaine, marketing it as coca-cordial, cocaine cigarettes, hypodermic capsules, ointments and sprays. Roche was heavily involved in the supply of morphine to the underworld and the Canton Road smuggling case — Shanghai, 1925 — revealed extensive involvement of Hoffman-La Roche in the illegal drug trade.

Thus "some of the great pharmaceutical companies of today owe their existence to profits from the trade in heroin and morphine in an era which laid the foundations for the self-perpetuating cycles of addiction to these drugs in modern societies. The next generation might look back on the activities of Hoffman-La Roche in pushing Valium and Librium with disgust equal to that we feel today towards their heroin sales between the wars".

The entire pharmaceutical industry is virtually controlled and dominated by private firms from four countries — USA accounting for 34 percent of world production, Japan 20 percent, and West Germany 13 percent, Switzerland 10 percent, Hundred pharmaceutical firms out of an estimated ten-thousand in the world account for 90 percent of world shipments of drugs; out of these the top 25 TNC's (half of them from USA) account for 50 percent of this sales (UNCTC, 1979).

In 1980, out of the 83530 million dollars production of drugs the developed countries (including East Europe) accounted for 88.5 percent and the developing countries only 11.5 percent (UNIDO, 1980). And within the developing countries India, Egypt, Brazil, Argentina and Mexico accounted for two-thirds of the drug production (UNCTC, 1979). As regards drug consumption the developed world consumes 80 percent and the developing world (including China) 20 percent of the world production (UNIDO, 1980) - an awesome irony when the population ratio is just the other way around. To quote Halfdan Mahler, "the public health services of the 67 poorest developing countries, excluding China, spend less in total than the rich countries spend on tranquilisers" (Mahler, 1981).

On an average drug consumption in some of the poorest countries works out to less than 50 pence per capita, whereas in some industrialised nations it is 35 pounds per capita (Faltorusso, 1981). These figures underline the lack of purchasing power of the third world poor. Essentially, they reveal more about wealth than health. It is, for example, highly debatable whether the level of drug consumption in much of the rich world represents a particularly 'healthy' state of affairs. But one conclusion is inescapable : whereas rich countries can afford to be extravagant with medicines without risking acute social consequences, poor people and their governments cannot. Because they have so little money, it is crucial that it is spent only on essential drugs (Melrose, 1982). Ironically, even the "little money" in the third world is largely spent on drugs which are not necessary at all — this is because of the overwhelming control of drug production and trade in these countries by the TNC's.

Thus as a consequence of this global oligopolistic control and domination (even in free enterprise USA 20 firms account for 80 percent of all drug sales) the pharmaceutical industry has established a position through which any amount of abuse may be hurled at the people without any adverse consequences to the former.

Braithwaite's book consolidates most of the earlier work since the early sixties and puts it together into a comprehensive whole. He also draws a great deal from the US Security and Exchange Commission (SEC) files and rounds it off with 131 interviews with executives of 32 TNC's in five countries. Braithwaite covers a whole range of crimes from simple payoffs and kickbacks for hastening administrative procedures to criminal practices in drug-testing and manufacture, from financial fiddling and oligopolistic practices to malpractices in drug pushing, and from smuggling and international law evasion to abuse of the third world nations.

This survey of pharmaceutical criminal undertakings is adequately supported by a wide range of case-studies from most of the prominent drug TNC's. Here is an overview of the crimes and a few of the case-studies recorded in the book.

Bribery

Bribery is considered as normal and acceptable business practice. "Almost every type of person

who can affect the interests of the industry has been the subject of bribes by pharmaceutical companies : doctors, hospital administrators, cabinet ministers, health inspectors, customs officers, tax assesors, drug registration officials, factory inspectors, pricing officials and political parties".

Braithwaite, after a thorough search of SEC files, lists 29 US pharmaceutical firms that have disclosed substantial amounts of questionable payments. No other industry, he adds, has anything approaching this record of *documented* corrupt payments, sustaining the conclusion that the pharmaceutical industry is more prone to bribery than any other international business. Possibly this is because like aerospace, arms, petroleum and other heavy capital goods industry, pharmaceutical firms deal with big win or lose situations — the new billion dollar product to be approved or the multi-million dollar supply contract to a third world government. Passing of a plain envelope of currency notes under the table is not the only method of bribing. In fact, most often more sophisticated methods are used. Braithwaite points out for instance, that if the secretary of a hospital board owns an architectural firm, a law firm, or a public relations firm, then you can hire his/her firm, perhaps even get some genuine services from it, but pay extravagantly for such services. You can even rent a property from the person concerned at an unusually remunerative rental. The pharmaceutical disclosures show that paying on an invoice to the company for services not actually rendered, or overinvoicing by the company so that an excess can be put aside for the recipient of the bribe have been the most commonly reported practices in the pharmaceutical industry. What is most interesting is that most questionable payments are treated as tax deductible expenditures which means a substantial loss to the state exchequer. For instance Merck, which reported 3.6 million dollars as qestionable payments in 39 foreign countries claimed tax deductions and after the disclosure agreed to pay the US Internal Revenue Service additional tax of 264000 dollars. Similarly Warner-Lambert had an additional tax liability of 325839 dollars.

Corruption often reaches highest levels of government as in the following incident reported in the New York Times : In Italy a dozen manufacturers, including some American companies, once banded together to back an industry sponsored bill in the Italian Parliament that would have allowed manufacturers to sell their non-prescription products in supermarkets and other retail outlets. There, they would no longer be subject to price control. One million dollars (80,000 dollars per company) were paid into a war-chest of the ruling Christian Democratic Party.

There is an even more interesting case involving Hoffman-La Roche, who bribed two Kenya government pharmaceutical buyers for favouring their products. *The two health officials were convicted and imprisoned and it was revealed that they had brought quantities of an anti-bacterial and a tranquiliser from Roche that would last the nation for a decade—not a healthy situation with products having a shelf-life of only couple of years.*

What has been done to curtail the menace of bribery ? Nothing of consequence is Braithwaite's conclusion. He cites the instance in Mexico when Portillo came to power. Eight top executives of pharmaceutical TNCs were arrested and jailed; also a number of senior government officials were dismissed. This raid was in reality aimed at launching a moralising campaign to turn into reality the aims set forth by the new government of the republic at Inauguration Day, as also to remove officials who would be a problem to the new government. Of course, after a few days the defendants were released on a bail of one million pesos each and some months later even the charges were dropped ! But such dramatic gestures cannot be sustained for long because once the international business community recoils from the shock and regroups, it is a worthy adversary to the state in instiutional power. Similarly in the USA the SEC disclosures have been firing blanks : who gets hurt in consent settlements ? The SEC gets a notch in its gun. The law firm gets money, the public is happy because they read 'fraud' in the newspaper and think criminality right away. The company neither admits or denies anything. Its the perfect accomodation. And its all one big charade.

Drug Testing

Bribery as a crime seems inconsequential when one looks into the fraudulent practices in safety testing of drugs and unsafe manufacturing practices of the pharmaceutical industry. The crimes in these two sectors have caused irrevocable human damage. At one end there is gross manipulation and cheating in drug research and on the other end cutting corners on product quality in the manufacturing process.

Morton Mintz's exposure of the frauds of the drug industry was a pioneering effort and set in an

era of greater vigilance towards illness-business. In 1962 the FDA made multiple seizures of Regimen tablets (phenylpropanolamine hydrochloride), marketed by the Drug Research Corporation as a 'reducing pill', on charges of misbranding. In depositions by two doctors who had 'tested' the drug it was revealed that the results were complete fabrications. For instance one doctor reported that her report was untrue in its entirely—57 of her 75 patients' charts were complete fabrications and of the remainder only the patients' initials and starting weights were correct ! (Mintz, 1967).

Two investigators in drug testing Dr. Bennett Robin, who had tested 45 products for 22 reputable pharmaceutical companies and Dr. Leo Cass, director of Havard Law School Health Services, who had undertaken 84 research projects for testing and 25 projects for product marketing applications were identified for scrutiny by the FDA. It was revealed that a substantial proportion of the 'testing' was *'graphited'*, that is, by invention of pencil, rather than by actual testing. The FDA revealed that many of the patients on whom 'tests' were done had been deceased earlier or were never hospitalised and treated. Also, for those who were treated the statements made, including claims that treated patients had certain medical conditions, were untrue. This was in the early sixties.

Even in the late 'seventies, after substantial tightening of regulations and monitoring by FDA, graphiting and distortion of results in drug testing were rampant. Between 1977 and 1980 FDA discovered at least 62 doctors who had submitted, manipulated or downright falsified clinical data. Add to this the fact that most fraud in clinical trials is unlikely to even be detected; most cases which come to public attention only do so because of extraordinary carelessness by the criminal physician.

The 1978 hearings of the Kennedy Sub-Committee on Health has catalogued a list of abuses which are still of major concern : (1) Case reports on fictitious subjects, and on subjects who were never administered the investigational drug; (2) Case reports containing the results of clinical laboratory work which was not actually performed; (3) False representation of Institutional Review Board approval of a study; (4) Misrepresentation of patient dagnosis and demographic data; (5) Consent (informed consent) of the clinical subject not obtained; (6) Drug doses given, farexceeding protocol limitations. (7) Drugs given to inappropriate subjects (especially pregnant women); (8) Serial use of investigational drugs to the exclusion of accepted therapy; (9) Administration to subjects of two or more investigational drugs at the same time and the administration of other significant and perhaps interfering drugs with the investigational drug ; (10) Inadequate medical attention to the test population through excessive delegation of authority, lack of follow-up; and (11) Representation of investigational drugs as marketed products and/or the sale of such drugs.

This (researcher dishonesty) is indeed an alarming situation but worse still is the situation in third world countries where consumer protection is almost totally absent. Drug companies opt to test particularly dangerous drugs in the third world because poor people are regarded as more dispensable, and in some measure this is undoubtedly true, concludes Braithwaite. But there are also other more practical reasons for going to the third world first with drugs for which fears of side-effects are great. *Peasants do no not sue global corporations for injury. Informed consent regulations for drug testing do not exist in the third world.* Moreover, given that the patent life of a new discovery is finite, and that monopoly profits will only accrue while the patent lives, there are incentives for companies to get a product registered wherever they can as early as they can. And if the product is found to be unsafe by subsequent, more sophisticated, testing in a developed country, then at least the company has made some money in the third world while the going was good.

Unsafe Manufacturing Practices

Pharmaceutical transnationals have a high reputation, especially in the third world, as regards their product quality and manufacturing practices. But Braithwaite cites a number of cases even within developed countries to prove that this is not wholly true. Yes, it is a fact that manufacturing practices of TNCs are relatively superior to those of other industries but in the third world their standards are very lax in part due to lack of well-defined standard codes in most of the third world.

Many countries have legislations pertaining to quality control such as Good Manufacturing Practices (GMP), Good Laboratory Practices (GLP) and Standard Operating Procedures (SOPs) but the legislations provide adequate loopholes, and monitoring and control is a fairly difficult process and therefore a very constraining task for the state

whose resources are limited. And as one quality control manager put it 'government inspectors ensure the quality of your records, not the quality of your deeds'.

However, there is no doubt that the worst quality standards are in the third world countries where due to limited resources short-cuts are invariably adopted. In the drug industry cutting corners on quality can have very serious consequences for consumers and therefore "bath-tub" manufacturing which is extensively prevalent in the third world, needs greater regulation. In fact, in many third world countries TNCs try to push up quality control - GMP and SOP - Standards because for manufacturers in the third world high quality means cost constraint, which in turn pushes up market prices and in a poor country high priced products could mean loss in market share. Higher quality standards puts the TNCs, who have virtual monopoly of high quality technology, in a domineering position, as well as assures them of a relatively competition-free market.

Drug Peddling

Most countries have restrictions about what claims are made about the products efficacy and use as well as regulations pertaining to Indications about side-effects about the drugs, and its contra-indications. However, as in the case of other areas the scope of malpractice in advertising is also greater in the third world revealing once more the double standards of the drug TNCs. The cost of promotion and consequences of criminal malpractices therein are ultimately borne by consumers. The UNCTC (1979) indicates that approximately 20 percent of all drug sales at the manufacturer's level goes for promotion. In the US the drug industry is easily at the top of league of the heaviest advertisers, with the soap and detergent industry its only close rival; even tobacco, alcohol, food and soft drinks lag well behind (Haslemere Group).

In the third world the expenditure is estimated to be even higher. In Columbia the money spent each year by foreign companies on marketing their drugs adds up to more than half the country's national health budget (Braun, 1980). The Concentration of sales representatives to doctors in the third world is much greater than in developed countries. In Britain, there is one medical representative for 18 doctors, whereas in Bangladesh the ratio is 1:7; in Tanzania 1:4; in Nepal, Brazil and Central American countries 1:3 (Melrose, 1982).

The Kennedy Senate hearings have documented gifts to doctors of freezers, tape recorders, stethoscopes, golf balls with Pfizer stamped on them; indeed, almost every type of consumer product imaginable. Further, in 1973, 20 drug companies in the USA gave 12.8 million gifts to members of health care profession and over two billion samples of free drugs. Drugs companies have provided free to 80,000 doctors in 35 cities F M radio sets tuned to the Physicians Radio Network that constantly churns out medical news and features of interest to physicians.

The major consequence of such heavy promotion of drugs is that where people have access to drugs there occurs a substantial amount of over-medication, especially of the non-prescription drugs that 'ease our ailing heads, noses, chests and bowels' giving us 'fast action and rapid relief'.

Oligopoly and Price Fixing

High profitability is the lifeline of the drug industry, contrary to what OPPI and IDMA would like us to believe. Since World War II pharmaceuticals has been the most profitable business. The UNCTC observes that from 1953 to 1967 in the US, the equity capital in drugs increased 584 Percent whereas for the entire manufacturing industry the increase was only 183 Percent in the same period. Most American companies have been recording on an average, net profit between 30 percent and 40 percent a year; SKF, Carter-Wallace, and Rohrer between 40 and 47 percent; Syntex, A.H. Robins and Marion Laboratories over 50 percent and Upjohn even during the depression between 1930-35 recorded an average of 30 percent.

Braithwaite rightly argues that excessive profits in the pharmaceutical industry arise in considerable measure from the peculiar features of the market which shelter producers from price competition. Consumer sovereignty is absent in the prescription drug market because it is not the consumer who makes a decision to purchase, but the physician. Doctors have no reason to be price-conscious. Moreover, the need for effective medical care is relatively price inelastic in affluent societies.

The Kefauver hearings before the US Senate Sub-Committee on Anti-trust and Monopoly (1977) found that the average production costs for 15 major drug firms were 32.3 percent of the wholesale price at which the manufacturers sold their product. Not one of the 50 companies compared

from other industries had production costs lower than the highest production costs among the 15 drug companies; only Coca-Cola came somewhere near with a production cost of 42.6 percent of ex-manufacturer sales.

Besides the drug market structure, the legal back-up of patent holding for 16-17 years makes the pharmaceutical industry oligopolistic. Patent-holding alongwith branding gives the pioneering company an advantage because the brand name becomes a habit and late-entrants to the market find it difficult to break the original brand's monopoly of the drug market. Thus the higher price of the brand-leader is no threat to its market share. As a result fortunes have been made because of patenting and branding, and quite often through direct oligopolistic deals as happened in the case of tetracycline, quoted at length by Braithwaite.

Pfizer and Cyanamid were dominating the broad spectrum antibiotics market till 1953 with their patents on chlorotetroncycline and oxytetracycline. This patent protection helped them maintain high prices and massive profits. But in 1953 when the therapeutically superior tetracycline came on to the scene their profits were threatened. Both the firms wished to avoid this competitive market structure and therefore manoeuvred a deal that managed to restrict tetracycline sales to five firms-Pfizer, Cyanamid, Bristol, Squibb and Upjohn — all of whom recognised Pfizer as the patent holder.

Thus price-fixing was inevitable. Keauver's investigations revealed a conspiracy that was in violation of the Anti-trust law of USA (The first charge was made in 1958 by the Federal Trade Commission). A long drawn out legal battle began which acquired an international dimension (including India). The various civil cases are still going on but criminal charges have been inconclusive. So far damage worth 250 million dollars have been paid by companies -- the US government itself is claiming overcharges of 376.5 million dollars.

However such price-fixing conspiracies are not possible today because all governments (USA being the only exception) have a price control policy. Of course, this is no guarantee that the pharmaceutical TNC's will not club together to influence what to their understanding is a fair price. Oligopoly has become the basic operating principle in the pharmaceutical industry. The most classic instance, ironically, being free enterprise USA itself. Inspite of the Anti-trust Law five massive mergers of pharmaceutical TNC's have taken place in the last decade or so: Mead Johnson and Bristol Myers; Plough and Schering; Ciba and Geigy; Parke Davis and Warner-Lambert; Dow and Richardson-Merrell.

Then, as the markets and courts have failed to regulate pharmaceutical prices effectively, and since self-regulation of pricing would be to put Dracula in charge of the blood bank, the only course, argues Braithwaite, is for greater political administrative price control.

Financial Fiddling

Financial abuse is an area of crime that probably has the worst consequences for the third world nations. Other areas of crime discussed earlier affect health of consumers directly as individuals or may be even as a class but financial fiddling can cause irreparable damage to a third world nations' economy.

For instance, a large proportion of transaction on the books of an international company, writes Braithwaite, are sales from parent to subsidiary, subsidiary to parent, or one subsidiary to another. Intracompany *transfer prices* can effectively shift profits from one part of the world to another. For example, drugs might be shipped from a high-tax country to a low-tax country at below market prices in order to shift profits to where they will attract least tax. Transfer pricing is therefore a classic law evasion strategy. Tax laws of the high-tax country are not violated, they are evaded. In one celebrated case vitamins were manufactured in France at a cost of Fr. 50 per kilo, exported to West Germany, from there sent to Switzerland, thence Monaco, and eventually reimported to France at Fr. 250 per kilo under a different trade name. It sometimes happens with such cases (especially in the third word) that shunting around the circuit happens only on paper without the corresponding physical movement of materials.

The most important tax heaven in the pharmaceutical industry is Puerto Rico. A large proportion of transactions between the USA and other parts of the world, comments Braithwaite, go through Puerto Rico. Wall street analyst John Buttles II calculates that Warner-Lambert had a 110 percent return on its investment in Puerto Rico plant and equipment in 1976. For Abbot the figure was 101 percent while for Schering it was a meagre 90 percent. In 1977, Schering recorded 59.2 percent of its world-wide profits in Puerto Rico; Squibb 53·7

percent; Abbot 48.4 percent; Smithkline 45.7 percent. But Searle outdid everyone: while Searle's worldwide operations in 1976 and 1977 ran at a loss (at least were shown as so) its Puerto Rico subsidiary recorded over 100 percent of its worldwide profits.

A study of third world countries shows that pharmaceutical imports into Columbia by foreign owned companies were overpriced by 155 percent, very much higher than the overpricing of other imports. Vaitsos estimates that if Columbia had been paying average world prices for its pharmaceutical imports, the country would have saved a charge of 20 million dollers to the Columbian balance of payment in 1968. Approximately half of 20 million dollars in excess profits repatriated by transfer pricing would have gone to the Columbian government in taxes (Vaitsos, 1974).

Besides fiddling books, repatriation of profits from third world countries can be achieved by fiddling packages. A European transnational was found to be importing into South America sealed packages of drugs which contained less than 30 percent of the declared contents. By paying 100 percent of the declared cost to the patent company (through a tax haven) the subsidiary was able to transfer 300 percent increased profits to the parent.

There are many reasons apart from evading tax, indicates Braithwaite, for a parent to charge high prices for intracompany sales to an affiliate, and low prices for sales from affiliate to parent. It might be done to circumvent dividend repatriation restrictions, reduce the affiliate's exposure to currency devaluation and expropriation risks, lower apparent profits when excessive profits might encourage labour unions to escalate wage demands and local customers (and governments) to demand price reductions, or simply to allocate markets by making the exports of a subsidiary noncompetitive.

Thus, if the control and domination of the drug TNCs has to be broken, their abuse of human health eliminated and their crimes in the manufacture and marketing of health terminated, the fight necessarily must be a political one and not one of improving the market and legal situations as most countries are resorting to today. The TNC power is derived from their ability to control and manipulate political affairs of both developed and developing countries. Only a manifestation of power of an equal force can offest the drug TNC's choking hold over people's health and well being.

Case Studies

(1) Richardson-Merrell : In 1960, a subsidiary in the USA began the marketing of a blood-cholestrol reducing drug, MER/29 (triparanol). In its first 12 months 300,000 Americans used MER/29. Soon reports flooded the market about its side-effects - baldness, skin damage, changes in reproductive organs and blood and serious eye damage including cataracts. It was later revealed that the drug had problems in the testing stage. On grounds of integrity, Mrs. Benhah Jordan had quit Merrell. There was gross manipulation of data in the animal testing (monkeys) programme and gross misreporting of facts to FDA, inspite of the fact that comparative studies by Merck and Upjohn had reported severe side effects. Even in the human testing stage doctors reported severe side-effects but Merrell chose to ignore them and fabricated the data for FDA approval. It was also revealed that the supervisor on the project. 'Dr' William King had not yet been awarded his medical degree! In the criminal case that followed the defendants pleaded 'no contest' and after six month's probation and a paltry fine (dollars 80,000) the three exceutives were let free. In civil suits that followed Richardson-Merrell paid 200 million dollars, mostly in out-of-court settlements.

(2) Dawes Laboratories : In 1971, many workers complained of sexual impotence — some men had developed enlarged breasts, in one case requiring surgical removal. Plant conditions were bad - ventilation was practically non-existent and the whole interior of the plant was covered with dust containing as high as 10 percent DES (a hormonal product) by weight. An enquiry by OSHA resulted in a fine of only 21000 dollars.

(3) Hoffman-La Roche : In a patent hearing in Canada it was revealed that the wholesale price of Valium is 25 times that of gold. It costs dollars 87 per kilo for the raw matrial for Valium (diazepam). To put the raw material into final dosage form and to label and package the tablets brings the cost upto dollers 487 (high estimate). The final retail price is dollars 11000 for that same original kilo which has now produced 100000 ten milligram tablets. The selling price is 140 times the original cost of materials and twenty times the total production cost. Roche sales of Valium in the USA alone in 1972 was worth 200 million dollars. Roche sells Valium in Germany at four times its price in Britain (both belong to EEC). In Sri Lanka Valium was quoted by Roche to the government as 70 times the price charged by an Indian company.

TRAGEDIES AND TRIUMPHS

Health and Medicine in Bhopal

padma prakash

March 23, 1985 : A premature baby, born two months too early died at the hospital at the DIG bungalow after a nine-hour unequal struggle to live. The mother was a gas victim and had brought the baby to the hospital five hours after its delivery by a dai. The child had been put on oxygen. The baby and the mother lay uncared for on the floor of the ward until 8 p.m. when a visiting pedaetrician just happened to look in on the doctor-in-charge. He was directed to the child. By then it was too late. No attempt had been made to clear mucous from nose and throat of the child and although the suction apparatus, dusty and rusted, did work, the hospital had no stock of small-sized catheters. The heart had stopped, the hosptial had only coramine which of course, was of no use. The child was declared dead and a certificate was issued. There was no post-mortem although it was actually a gas-related death. The mother had attended the ante-natal clinic of the hospital three weeks before and had been given an injection — presumably TT, but had not been given any advice about her pregnancy or the necessity of a hospital delivery especially if premature.

March 24, 1985 : A seminar on Pulmonary Medicine was organised at the Gandhi Medical College, (GMC) Bhopal. The afternoon session was on effect of MIC on the lungs. There were several eminent speakers — Dr. S R. Kamat of the K. E. M. Hospital, Bombay rapidly projected innumerable slides and summarised his findings on treating 113 gas-hit patients who had been admitted to the hospital. Prof. Heeresh Chandra, head of the Forensic department of GMC talked of autopsy findings screening slides which even his colleagues at the college had not been allowed to see until then. His findings, he said, pointed to cyanide poisoning and vehemently advocated detoxification with Sodium Thiosulphate (NaTS). Dr. N. P. Mishra peppered his presentation with long quotes from medical researchers from UK and USA to whom he had written. He declared that the gas victims had died of carbon monoxide poisoning. His own trials with NaTS showed that it caused a reaction— two out of 200 patients developed gastrointestinal symptoms and rashes — and so he was opposed to NaTS. There were many others — all of them taking great pains not to reveal the full details of their studies. In the discussion that followed everyone seemed to forget that the focus here was not a scientific thesis but the future and death of lakhs of people.

Sitting in that lecture hall one could easily forget the larger theatre of disaster across the city. These two events illustrate the emerging situation in Bhopal. In the gas-hit bastis the nightmare of December 3rd continues to haunt the people — their health is deteriorating, state-run medical relief is almost at a standstill, equipment is inadequate, information supplied is nil, doctors are uncaring and in any case, no medicines help. In the hallowed halls of medical and scientific institutions researchers are engrossed in intricate debates to prove their favourite hypothesis quite losing track of immediate concerns. The macroworld of two lakh suffering people has been reduced to the microcosm hundred of odd hospital patients in the 'MIC wards'. Typically the medical profession has transformed the stupendous medico-social situation into a laboratory-based clinical/medical problem.

Reviewed here is the health picture in gas-hit Bhopal as it has developed during these months and the manner in which the medical community has responded to it.

The Black days

The Bhopal disaster has been called the world's worst industrial disaster, and with reason. The number of dead mounted in terrifying proportions — 350 by the end of December 3, 500 by the 4th, over 1600 by the 5th December. One week after the disaster a conservative estimate put the death toll at 2,500. Unofficial estimates put the numbers closer to 6,000. But the exact numbers will probably never be known.

By the end of the third day over 20,000 people were being treated in the city's seven hospitals. They came with complaints of burning eyes, lacrimation, cough, breathlessness, nausea and dizziness.

That first day alone saw over 10,000 patients in one hospital showing signs of eye damage.

Bhopal's 350-400 doctors worked round-the-clock at numerous centres — make-shift tents, medical aid posts and the wards. Hospitals ran out of medicine and had to buy out stocks from the city's shops, oxygen had to be obtained from other cities. A hundred more doctors were brought in from the near-by towns.

For a time no one knew for certain what the killer gas was. Some said that it was methyl isocynate, others phosgene. None of the doctors knew how to treat the victims.

It is now known that the Union Carbide (UC) knew of the results of six animal studies initiated by the company which provided enuogh evidence of the chemical's high toxicity. (Three of these listed in the Box) Moreover the Occupational Health Guidelines for MIC states clearly that MIC might well decompose into hydrogen cyanide, oxides of nitrogen and carbon monoxide at high temperatures (of over 200°C). UC's own standard line of treatment prescribes intravenous hydrocortisone, oxygen inhalation and if cyanide poisoning is suspected then amyl nitrite. If there is no effect, sodium nitrite and NaTS are to be administered. Yet, in the first week when Bhopal's doctors desperately needed information to save lives UC held back vital information.

Many of the doctors of Hamidia were on the Carbide plant's medical panel. Also UCIL had been giving generous funds to the hospital and GMC and had set up a respiratory research unit and ward. This indicates a close enough association between at least some of the hospital doctors and the plant's medical personnel. It is curious that the former did not know of the standard line of treatment for such 'accidents' which had apparently been long established at UC.

By all accounts the efforts put in by hundreds of people — the doctors, nurses and medical students, the army, the police, the NSS and the NCC volunteers and voluntary groups — in that first week was of heroic dimensions. (Many of them later suffered from delayed exposure to MIC). But the government machinery took time to dissociate itself from the electioneering, recover from the shock and coordinate relief measures.

Operation Cover-up

By December 6th it was, as one writer put it, 'back to business' for government doctors and others. Private doctors and nursing homes were also minting money and death and medical certificates were being sold at thousands of rupees. Hordes of experts began to arrive in Bhopal and everyone who was anyone began to make statements about the consequences of exposure to the gas. Speculation about the real nature of the gas ran rife. And the government put an embargo on information. Even the death toll was not revealed on the grounds that 'it was not advisable in public interest'.

Autopsies were performed from the third day but reports were not released. They showed fluid-filled lungs two-to-three times heavier than normal, ulcerative changes, cherry red appearance of organs, arterialisation of blood .. ... To Dr. Heeresh Chandra the autopsy surgeon, they indicated cyanide poisoning.

Even as experts in the government and outside it glibly began to assure people that there would be no after-effects, many people who had earlier been treated and discharged began to come to hospitals with new symptoms — shivering, yellow appearance, dryness of mouth, vomiting, nausea, stomach ache, diarrhoea, skin irritation and headaches and more seriously, conditions like cerebral palsy indicating the involvement of the central nervous system. More than 1,000 patients were on the critically ill list and at least 50,000 had serious eye problems. Some estimated that at least 500 of them would go blind but others like Dr. N. R. Bhandari, the superintendent of Hamidia Hospital said that there was no cause for anxiety and that the blurring of vision was due to the administration of atropine. "The worst is over" he stated and ruled out the possibility of the gas affecting the brain. Dr. M. N. Nagu, Madhya Pradesh's director of health services said that there might be ulceration and appealed for eye donations so that corneal grafting facilities could be offerred.

Scientists from UC's Research and Development centre stated that the gas would be excreted from the body in due course and only bronchodilators were necessary. Scientists at the Industrial Toxicological Research Centre (ITRC) Lucknow opined on the basis of their study of literature that there would be no further damage because of the gas. And agricultural scientists were reassuring people that there was no environmental damage and cautioning them to only make sure that vegetables were washed, water and milk boiled before consumption.

With thousands still suffering from debilitating symptoms the only treatment being meted continued to be symptomatic — eye drops, antibiotics and corticosteroids. Interestingly, the WHO toxicologists approved of the then current of treatment and insisted that there was no known antidote for cyanate poisoning. Two lone voices were heard to assert that there was antidote which seemed to be effective — NaTS. One of these supporters of NaTS therapy was Dr. Max Donerer, a German toxicologist who had arrived in Bhopal with ampoules of NaTS and had started using it. The other was Dr. Heeresh Chandra who on the basis of his autopsy findings believed that NaTS would be effective and had taken it himself. When two patients who had been given NaTS died, the German was quietly packed off. NaTS therapy was discontinued much to the relief of UC's Dr. Loya and his supporters Dr. Mishra and Dr. Bhandari Dr. Chandra was methodically isolated and ignored. Why was NaTS therapy discarded so precipitously? The deaths it appeared, were merely excuses, because the real cause was never investigated. Also curious is the fact that no one seemed to have questioned why the second telex from Union Carbide reversed the advice given in the first to administer NaTS. One of the arguments against using NaTS was that although there was evidence that people who had been administered NaTS seemed to recover, there was no 'proof' that it worked! The history of medicine has seen any number of situations when a therapy which has been found to be effective has been used because it is needed and only years later has the mechanism of its action in the body been worked out. The tragedy of Bhopal is that it is now acknowledged that thousands of lives could possibly have been saved if detoxification with NaTS had been undertaken in those first days.

By the end of the first week operation cover up was well on its way. The panic-stricken state government seemed more concerned about absolving itself of any responsibility for the disaster than about helping the victims. What is most shocking is that a section of the medical community collaborated with the government in keeping medical information under wraps. There was deliberate falsification of records, x-ray and pathological reports were refused to patients, autopsy reports were not given to those concerned. In normal times such a gross disregard for ethical practice would have been soundly condemned. But in Bhopal it was and is justified as being in the interest of controlling public panic and anxiety.

Expert vs Expert : While people suffer

A full eight weeks after the disaster the deleterious effects of the gas were still evident. New signs and symptoms were appearing — damage to the liver, kidneys, gabrahat, anxiety, depression, loss of memory, confusion and lack of co-ordination deafness and impotency. By the end of the second week there had been 800 doctors working in Bhopal's 64 round-the-clock medical centres. But two months after the disaster most of the state-run operations were winding down. Mobile hospitals were still plying but people had generally realised the ineffectiveness of medicines. Many had turned vendors of antibiotics, antacids and vitamins. At no time had any attempt been made by the government agencies to give medical and health information to the public. People were distraught and confused. Controversies abounded and the situation was made worse by the cloak of secrecy.

Earlier the team sent by the Royal Commonwealth Society for the Blind had asserted that no permanent damage or blindness was likely to result. American opthalmologists were of the opinion that opacities were highly likely to develop in the centres of the corneas thus affecting sight.

The ITRC team reported that the delayed effects and neurological symptoms perhaps indicated the presence of phosgene as well. They also reported that pulmonary fibrosis was a possibility in the survivors. American experts saw clinical evidence of diffused lung damage. Others denied that there could be any permanent damage — they attributed the high incidence of lung complications to the previously existing high rates of tuberculosis and other chronic lung problems. In Bombay Dr. S.R. Kamat was reported to have found evidence of permanent pulmonary damage, of changes in haemoglobin and neurological damage in gas-affected patients at the K.E.M. Hospital there. These patients were put on levamesol (so far used as an anti-helminthic) and the results were said to be promising. But the full report is yet to be published or presented.

Around this time another controversy which had been brewing for some time erupted. And it reads like a horror story. Since the second week there had been reports of stillbirths and abortions among the affected pregnant women. Some Hamidia doctors had reported finding traces of phosgene in the aborted foetuses. Abortions in gas-hit animals had also been recorded. Defence Ministry sources were quoted as saying that MIC was known to cause

damage to the foetus. Although the Sultania Zenana hospital had set up a special antenatal unit, most of the distressed and anxious women were turned away with assurance that the babies were safe. A survey in February / March of 1,900 households showed 100 cases of abortions and 22 stillbirths. Neither the government nor the medical pundits were willing to concede that there just might be some danger to the foetus either directly because of the toxic gas or indirectly because of the mother's health conditions. Given the state of knowledge at that time all one could have done was to offer facilities for amniocentesis examination and ultra-sonography and abortion services to those who opted for it. This did not even necessitate a stand being taken on whether MIC affected the foetus or not. But the authorities consistently brushed away these suggestions made by activist and health groups. When the Medico Friend Circle fact-finding team report in February suggested such a course of action, the bigwigs of medicine came down heavily on it for causing 'unnecessary panic'. In February two members of the Medico Freind Circle conducted a clinic-based study of gynaecological problems among the affected women in two bastis. They found high rates of menstrual disturbances, non-specific white discharge and evidence of pelvic inflammatory diseases. Up until then these conditions had neither been recorded nor reported. But again, no efforts have been made to set up special basti-based clinics or centres for women.

Medical Research in Bhopal

Not until January did the ICMR and other research agencies meet to work out the strategy for studying the impact of MIC. In the same month irked by the heavy atmosphere of secrecy leading newspapers had carried severe editorials criticising the ICMR's unwillingness to divulge relevant information. Perhaps as a result of this or because the lines of authority had now become clear, the ICMR released a first report on Bhopal. Unfortunately the report said little but listed out the various projects which had been approved. Surprisingly no comprehensive plan of research has been prepared nor priorities determined ! Research projects have apparently been sanctioned on ad hoc basis. Despite the Director General's earlier announcements there was no large-scale epidemiological survey listed. Earlier the MP government had instituted a detailed medico-social survey by the Tata Institute of Social Sciences in Bombay under strict surveillance and superivsion of the government authorities. For some unstated reason only a small portion of the survey was reported to have been completed, the rest being taken over by the government. And so there will never be a full-scale epidemiological survey of the consequences of the world's worst industrial disaster.

According to the ICMR's latest update, it has funded twenty projects with a total budget of over 156 lakhs. Only three of the projects are of less than two years duration. ICMR's ad hoc approach will certainly result in a series of research monographs years from now, but how much will it help the affected population ? In all likelihood they will never even hear about the results. The ICMR should have made it manadatory for all projects which dealt directly with the affected population to include a 'health education' component. If it had, we would not have the situation existing today of people being prodded, poked, examined x-rayed, and bleeded but never being given any information or advice about their health, their pregnancies. Bhopal's affected population is being treated by researchers as a set of guineapigs in a gigantic laboratory.

In the middle of February the ICMR finally released the results of its NaTS double-blind trial and issued a notification recommending NaTS to those in whose families death had occurred; those living within a radius of two km of the factory and those with specified symptoms such as nausea, tachycardia (high pulse rate), anorexia (lack of appetite) and so on. But the state government took no action on this until April when the ICMR issued a further set of guidelines. The centre could undoubtedly have acted to get the state to implement this decision. But it has conspicuously and distressingly kept out of the health scene in Bhopal.

There are some in the scientific and medical community who believe that debate on scientific and medical issues must be confined to the pages of scientific journals or seminars. The establishement's desire and its need for controlling information supports this archaic notion. In Bhopal this combined stand of the state and the professionals has had disastrous consequences for the people.

(Most of this material has been drawn from articles in newspapers and periodicals written by a number of people. Some of them are Kannan Srinivasan and Kalpana Sharma, Indian Express, Radhika Ramaseshan and Jyoti Punwani, Sunday Observer, Praful Bidwai, Times of India, Darryl D'monte, Illustrated Weekly and Arun Subramanyam, Business India. Other material utilised : ICMR's Update on Bhopal, Rani Bang and Mira Sadgopal's report of the study of gynaecological problems, MFC fact finding team's February report, ICMR's press releases and minutes of the February meeting.)

(Contd. from page 37)

In Britain, Roche was sued for abusing monopoly power by its pricing of Valium and Librium. In out-of-court negotiations in 1975 Roche agreed to pay 3.7 million dollars for over-pricing their product in the previous live years and also agreed to reduce the price at half the level of 1970. The importance of this case was that it focussed international attention on overpricing and anticartel suits followed in various countries.

(4) Upjohn and A. H. Robins : Upjohn's Depo-Provera, an injectable contraceptive for women, was found through early American research to be associated with such a welter of side-effects that the FDA has not only indicated that the product is not approvable in the US, but has forbidden human testing of the drug in the US. But huge quantities are being dumped on the third world. Throughout Central America one can walk into a pharmacy and purchase Depo Provera without a prescription. Earlier even most of the testing of the drug was done in third world countries like Brazil, Thailand, Chile, Philippines, Sri Lanka, Hong Kong, Egypt, Honduras, Peru, Mexico and Pakistan. "When research into its possible effect on the weight and blood pressure of women taking the injections was carried out in South Africa, the researchers saw fit to examine these features by experimenting with Negro (75 percent) and Asiatic (25 percent) women, rather than on women with the same coloured skin as the researchers".

Similarly A.H. Robins has dumped Dalkon Shields, an IUD, in some 40 third world countries. It was recalled from the American market after 17 women were killed. In an enquiry later it was revealed that in the teststage physicians had reported unfavourable effects like uterine perforation and ectopic pregnancies.

The staggering thing about the dumping in the third world in this case has been the involvement of the US government's office of Population with the AID. USAID purchased the contraceptive device at discount rates for assistance to developing countries after the product was banned in the US. Double standard for third world consumers were even more remarkable when Robins sold USAID unsterilised shields in bulk packages at a 48 percent discount. USAID justifies the discount Dalkon dump on the grounds of getting more contraception for the dollar.

Why The Scope of SHR Should Be Confined to Health & Medicine

Anant Phadke and Dhruv Mankad

The sharp yet substantive comments on the first issue of SHR by Imrana Quadeer and Bharat Patankar/Jogen Sengupta (in "Dialogue" SHR 1.3) are welcome and raise hopes of SHR becoming a forum for debate also. We are responding to Imrana Quadeer's criticism to clarify and defend the standpoint taken by SHR to restrict the scope of SHR to discussion on Health and Medicine. At the same time we offer some critical comments on the material published in the first two issues.

Though we agree with many of Imrana's points of criticism and with her plea for greater analytical rigor, we want to point out that the errors she has pointed out do not flow from the decision of SHR to restrict itself to health and medicine. Her criticism on this point flows from her own confusion.

The dominant bourgeois ideology considers Health and Medicine as primarily technical issues; and if and when it considers social aspects, it glosses over, hides the role of the essential relations ("economic base") and the class struggle flowing from it. On the contrary in the first issue the Editorial Policy of SHR clearly states our standpoint that "From a marxist standpoint, health can be considered as a part and consequence of economic, political and socio-cultural development of society..." (three more sentences on similar lines). Any discussion on Health and Medicine within this perspective would necessarily be based on an understanding of society in general. Within the left, different individuals, organisations have differences in their understanding of the society in general and these differences would naturally reflect in their analysis of issues in Health and Medicine. A rigorous, correct understanding of Health and Medicine would not be possible with a superficial understanding of society and hence Quadeer is mistaken when she says that "It seems to me that a debate concentrating on health and medicine alone, however rigorous, tends to treat these general concepts superficially." If somebody disagress with a particular piece of analysis of Health published in SHR, one can show how that analysis is wrong by discussing that particular issue in Health and may also comment upon the basic understanding of the person being criticised but there is no point in having a debate in SHR on the nature of the Indian State, or of imperialism. Debating on concrete levels is not "an easy way out" as Quadeer thinks. Since a discussion on health and medicine within the left is relatively new, it is a more difficult path chosen by SHR compared to the option of publishing in SHR debates on general issues in Marxism. Let us illustrate our point by taking the same example of Amar Jesani/Padma Prakash's article

The main weakness of this article is not that it has focussed on "Health and Medicine alone", but that, on the contrary, it has unnecessarily spent about three pages on some of the details of questions like the strength of the Indian bourgeoisie, the strategy of economic development after Independence and so on. This exposition of strategy of economic development is not organically integrated in their analysis of health and medicine in post-colonial India. For example, for their discussion of malaria and tuberculosis control programme, the details about number of strikes on the morrow of Independence, or evictions of tenants during the agrarian transformation etc were not necessary. The space devoted to these details could have been better spent on arguing as to what exactly was wrong with these health programmes, what were their contradictions and so on. We are only told that they are death-control programmes (is this bad?) and that they have been used to divert the attention of the people by equating disease eradication to technical measures. It is not made clear as to what exactly is wrong with these programmes. Would not there be a malaria control programme or BCG vaccination in a socialist society? Is it that the programme was correct but that its purpose and ideological use is being criticised ? Or is it that the theoretical basis and the very organisation of these programmes is also being questioned? We need to take community medicine much more seriously. We need to study and identify how bourgeois ideology, interests, seep into the existing discipline of community medicine, and how a marxian approach can remedy this discipline into a fully scientific discipline which in turn would lead to appropriate health-interventions as an adjuvant part of socialist transformation. If this is done, (and this is "not an easy way out") our criticism of the existing health-system would be much more substantial and concrete. (This is of course a collective responsi-

bility of all of us and hence it is not at all question of merely pointing out mistakes of those who have ventured to come forward with whatever analyses they have.) However, we also believe that a rigorous analysis of the concrete — Health and Medicine— keeping in mind its dialectical relationship with the society at large should and can point to the general direction of one's analysis of the society as well. Amar-Padma's article fails to do so. Instead their analysis of health and medicine is disjointed from their analysis of Indian society. The two analyses are merely juxtaposed without any obvious inter-re'ationship having been established. It is a much more demanding task since in India, such questions have so far not been discussed within the left with any depth.

What is the implication of Quadeer s suggestion not to leave out issues of wider social order? To continue to take the case of the article by Amar Jesani/Padma Prakash; such a suggestion would logically mean that if somebody does not agree with (for example) the authors' analysis of the strength and independence of Indian bourgeoisie he would go into that question and put forward a criticism and give an alternative. SHR would then read like an EPW, or a Social Scientist; and not a journal on Health and Medicine. On the other hand she could concretely analyse the health issues from one's political point of view and present an alternative view on political economy of health, thereby refuting at the same time the author's viewpoint regarding e.g, the strength and independence of Indian bourgeoisie.

Those "doctors and other health-workers who were attracted to marxism because in it we found a better approach to handle our own contradictions and for relating ourselves to the wider society..." would definitely find SHR very meaningful if it contains analysis of their own field from a wider perspective of historical materialism. The first three issues of SHR have demonstrated this by analysing different aspects of health and medicine on a wider basis without however getting involved into a discussion on the mode of production or the nature of the Indian State. We very much believe that the concepts of historical materialism need to be grasped and used accurately, rigorously (otherwise one makes statements like -" since a mode of production is reproduced not only at the economic but also at the political and ideological levels..." a statement betraying confusion between "mode of production" and "social formation.") but it is not the task of SHR "to develop an analysis of society as well."

Articles in SHR need to be accurate on the technical matters as well. We would only register our strong reservations about C Satyamala's analysis of dysmenorrhea (painful menstruation) See her incorrectly titled article: *Is Medicine Inher-(ently Sexist*? SHR I : 2) At least our textbooks and teachers did not teach it the way Satyamala has put it. We also want to register our surprise about the way Srilatha Batliwala (Rural Energy Situation) SHR 1:2 has arrived at the caloric intake of a family (pp 75) and used it as a basis for her startling conclusion of a daily deficit of 100 Calories for a woman and a surplus of 800 Calories for a man. One can't take up these questions in this short letter. We hope, somebody else would take up these questions in some detail.

Attention SHR Readers !

As you know we have the honour of printing SHR and we hope you like it.

We would like to introduce ourselves as a different kind of business venture : give special service attention to socially-oriented individuals, groups and organisations. Besides being reasonably priced we undertake total proof-reading responsibility and help you in designing lay-outs and overall production of material. We also do the posting of publications from Belgaum on your behalf, if desired. All this means a lot of burden off your shoulders and more time for you for more creative work. So, if you have anything in mind for publication, do write to us.

OMEGA PRINTERS, 316 Dr. S.P. Mukherjee Road,
Belgaum 590 001 Karnataka Tel. 24124

RACE AND HEALTH CARE

Perspective from Chicago

bindu t desai

In the past 30 years the US expenditure in health care has multiplied several times now amounting to more than one billion dollars per day. This fantastic growth has not led to a closing of black-and-white health differentials. The health care system mirrors the racism and inequalities in American society. This article begins with a 'tour' of a medical centre complex in Chicago's financial and business district where the racial divide from a white, private luxurious hospital to a non-White, public, run-down hospital is unashamedly acknowledged. It goes on to show how black health statistics which had improved are now undergoing a reversal, and the Reagan administration's health budget cuts drastically affect the poor and the blacks. The oppression and exploitation of racial minorities is not unique to the US. The status of blacks in the US and the treatment meted out to them has obvious parallels to the situation of dalits in India. This article, we hope will motivate similar studies of casteism, communalism and sexism in the Indian health sector.

The United States and South Africa are the only two industrialised countries in the world lacking a system that guarantees medical care for all who need it. The past 35 years have seen an exponential growth in the United States both in the general economy and in the expenditure on health care which by itself now amounts to more than one billion dollars per day (Blendon and Altman, 1984). This growth has not led to equal access to health care or to a closing of black-white health differentials.

This perspective will examine health care in the US at different levels. First we will tour the conglomeration of hospitals and universities known as the Medical Center on the west side of Chicago. The outward differences noted on this tour will be shown to accurately mirror the larger racism and inequality in American society. We will then examine population-based health statistics as they pertain to race. After discussing medical education and affirmative action (the rough US equivalent of a reservation system in medical schools) we will analyse future trends in US health care.

A Tour of the Medical Center

About a mile west of the Loop, Chicago's financial and business district, lies the sprawling Medical Center complex comprising two medical schools, four major medical institutes and said to contain, with typical American hyperbole, "the largest collection of medical expertise in the world." The apex of this medical pyramid is the Rush Medical school with its Presbyterian-St. Luke's Hospital (PSL).

This complex occupies six buildings, four of which were built in the last 10 years, elegant hulks of steel and aluminium, spacious, airy, the newest resembling a Hyatt hotel, complete with an atrium and indoor plants. Across the street from PSL is the bottom of the pyramid, Cook County Hospital (CCH). Consisting of eight buildings, a complex built at the turn of the century, CCH is the only institution for the poor of the Chicago area. Unlike PSL there are no carpets in the foyer of CCH, no cushioned chairs either. *When one crosses Harrison street, one crosses the racial divide in the US from a white, private, luxurious hospital, to a non-white, public, run-down, hospital.* A casual visitor cannot fail to notice that something very fundamental has changed in that short walk across a street.

A block away from CCH is the Abraham Lincoln School of Medicine affiliated with the University of Illinois (U of I) Hospitals. The medical school and hospital are run by the state of Illinois. They too have spanking new buildings, neat columns of cement and glass that are centrally air-conditioned, along with old red brick structures that house the prestigious Neuropsychiatric Institute and the old hospital. At the south-west edge of the Medical Center is the West Side Veterans Administration (VA) Hospital, an institution run by the federal government. The U of I hospitals and the West Side VA form the body of our pyramid.

These four institutions cover the different types of hospitals in the US except for the newest and fastest growing type of hospital — the for profit hospital — a separate entity in itself which we will discuss later. PSL dominates the area in terms of the facilities offered to the patient, both those providing physicial comfort and the latest in medical investigative technology. At PSL there are no long waits in the Emergency Department (ED). The patient is admitted to a private or semiprivate room with an attached bathroom, each bed has a television set, a

telephone, and the hospital is centrally air-conditioned. A patient who requires an x-ray procedure or a visit to a subspeciality clinic is seen without long delay. The waiting rooms of these clinics are cheerful, provided with magazines, and so on.

In contrast, CCH patients often have to wait eight to ten hours before being seen in the ED. As the hospital has very few semiprivate rooms, most of the patients are in a large general ward. The wheel chairs could very easily be exhibited in the Smithsonian's museums, patients share a common bathroom, bring their own television set or radio and may use the few pay telephones that are available in each ward. Except for the Intensive Care and Trauma units there is no airconditioning. The many buildings of CCH are unsatisfactory both in summer and winter. The wards are stuffy and hot in summer and draughty and cold in winter. Leaky ceilings and falling plaster are not uncommon. In fact the author's office, which is on the third floor of an eightstory building, was flooded after a thunderstorm and many books and journals were damaged! The patients at CCH wait for nearly everything—wait to be seen by a physician, wait for the diagnostic tests to be performed, wait for their medicines, wait in the corridors and hallways of the hospital. No magazines are provided for these patients.

CCH patients also have to wait before a Health Systems Agency grants a certificate of need for expensive x-ray equipment. The hospital was amongst the last in the Chicago area to obtain a CT scanner and paid PSL nearly 500,000 dollars per year to use PSL's scanner. Presently PSL already has the equipment for Magnetic Resonance Imaging so that the trend of an "underfunded public hospital spending some of its scarce resources to enrich an already wealthy private institution continues" (Schlosser and Cohen,1981). PSL and CCH are the two ends of the pyramid - the apex rich and powerful serving largely white patients, the base poor, relatively powerless serving largely black and Spanish-speaking patients, mostly from Mexico and Puerto Rico (Latinos). The U of I and Westside VA fall somewhere in between these two extremes in their facilities and equipment though in neither hospital are the patients forced to wait long hours in crowded halls nor do they have to be in a large general ward.

Since 981 when President Reagan began cutting back on health expenditures, CCH has seen a phenomenal rise in outpatient visits and transfer of patients from other hospitals. Outpatient visits have gone up from 114,262 in the first quarter of 1981 to 150,146 in the same period in 1984, an increase of 24 percent whilst transfers of patients, largely because of lack of third-party payment whether by private or governmental agencies, have gone up from 110 a month to 900 a month (Pharmacy Newsletter, 1984). There is the typical capitalist picture of smaller private hospitals closing units and laying off or dismissing staff whilst CCH becomes more and more overcrowded (Kotulak, 1984).

Let us now leave the Medical Center and survey the larger issues that determine the architecture, the distribution and the racial composition of the complex.

A Portrait of the USA

a. Demographic : The black population, which has risen from 9.9 percent of the total in 1950 to 11.7 percent in 1980, forms 26.5 million of the US total of 226.5 million people. The Southern states of the US account for more than half of the total black population, 14 out of 26.5 million. Blacks have moved from the rural areas to the centre of cities and the suburbs, whereas whites have moved out of the centre of cities to the suburbs. In the past two decades the population of farm workers who are black has dropped from 16 percent to 4 percent. In 1970 seven major cities had a black majority compared to seventeen in 1980.In an additional 13 cities blacks comprised 45 percent to 50 percent of the total population.

The seventies saw a decline in the number of male-headed family households from 73 percent to 63 percent and an increase in the number of households headed by women, for blacks it rose from 31 percent to 47 percent, for whites from 8 percent to 13.5 percent. Fifty-five percent of all black children were born to unmarried mothers compared to 9.5 percent of white children. Forty-two percent of all black children lived in two-parent families compared to 83 percent of white children. Forty-four percent of black children were living only with their mother compared to 13.5 percent of white children. Moreover, the marital status of these mothers differed considerably by race: 29 percent of the black mothers were single, 37 percent separated, 9 percent widowed and 25 percent divorced, whilst the figures for whites are 7 percent, 29 percent, 12 percent and 52 percent respectively

b. Income : In 1975, the peak of a 25-year upward trend, median black family income was 62 percent of white family income. By 1982 it had dropped to 55 percent. Black families with incomes

under 10,000 dollars rose from 36.5 percent of the black total in 1970 to 40.5 percent in 1980, whilst the figure for white families remained stable around 16 percent. In the past decade, the poverty rates have gone up for all races, for blacks from 31.4 percent to 35.7 percent, for Latinos from 22 percent to 28.4 percent and for whites from 8.4 percent to 12.1 percent (Pear 1984). The income gap between black and white families varies with the composition of the household and work experience. When a family has two earners black median income is dollars 20,000 compared to dollars 25,000 for whites (81 percent of white income) whereas for a family headed by a woman, black median income is dollars 7,425 compared to dollars 12,000 for whites (62 percent of white income) (Hacker, 1983).

Seven-and-a-half percent of black families earned more than 35,000 dollars compared to 17.5 percent of white families. At the highest income levels in excess of 75,000 dollars there were 548,000 white men (0.6 percent), 11,000 white women (0.01 percent), 4,000 black men (0.03 percent) and less than 500 (0.004 percent) black women. The programs of the past 20 years that were meant to aid minority businesses have had little impact. *The total assets of all minority business amount to less than 1 percent of the assets of the Bank of America alone.* The top 100 black business listed in Black Enterprise together have assets less than that of the 500th corporation listed in Fortune Magazine's top 500 corporations (Stokes, 1981).

c. **Employment :** The overall unemployment rate which was 7.1 percent in June 1984 is 18 percent for blacks and 4.3 percent for black teenagers. The proportion of black males participating in the labour force has declined from 83 percent in 1960 to 71 percent in 1980; whereas that for black women increased from 48 precent to 53 percent, and for white women from 37 percent to 51 percent. *Black Americans are over-represented in poor paying jobs such as garbage collectors (55 percent) and household servants (54), whereas they form fewer than 1 percent of all elected officials, engineers, lawyers and 2.6 percent of all university professors and physicians.* The public sector is a relatively better source of employment for black college graduates. Fifty-seven percent of black male college graduates were employed by the government, compared to 27 percent of whites. The figures for women are 72 percent of blacks and 56 percent of whites respectively. Whilst blacks comprise 14 percent of the federal civil service they form 30 percent of the army and 20 percent of all US defense forces. These percentages have doubled in the last decade. However only 5.6 percent of the officers are black. Black employment in the public sector is a matter of necessity. The US labour market is generally manipulated by big business to keep blacks out of private sector jobs. They are discriminated against in hiring and are forced to take lower paying jobs regardless of their qualifications. For instance, black women with education similar to white men earn only half as much as white men, and earnings of black men are 70 percent of an equivalently qualified white worker. Blacks have low seniority because of past discrimination where certain trades did not admit blacks to their rolls, and they have less work experience because of unemployment and denial of equal training and educational opportunities. If there were equal opportunity in the labour market the black-white ratio of per capita earning would be 89 percent instead of 58 percent. The estimated losses due to employment discrimination exceed by a factor of 11 the estimated excess welfare payments to blacks (Swinton, 1983).

d. **Crime and punishment :** Blacks formed 22 percent of the total number of arrests made in 1980 and 48.5 percent of a total state prison population of 272,348 in 1981. The US black imprisonment rate of 498/100,000 population for 1981, which can be compared with South Africa's 471/100,000 for 1976. (King and Whitman, 1981), is the highest in the world. The US white imprisonment rate is 75/100,000. *Forty percent of the prisoners on death row are black.* Since 1930, when records were first kept, 405 blacks have been executed for rape compared to 48 whites. This figure does not include the men lynched by white mobs.

e. **Education :** In the past 15 years black enrollment in colleges has doubled from 5 to 10 percent. Although 70 percent of their parents had never attended college and 45 percent had not finished high school, these parents by working at two jobs and so on have guaranteed their children higher education which they themselves were deprived of. Government programs have also played a role but the Reagan administration has cut back aid and reduced spending for disadvantaged students by 17 percent and on loans by 27 percent (Pear 1984). Twenty five percent of black college graduates, 20 percent of high school graduates and 30 percent of high school dropouts were unemployed compared to 6.6 percent, 6.4 precent and 16.4 percent (respectively of whites). For black students 45 percent do not complete high school, another 30 percent graduate from high school and 25 percent go on to

college, whilst among whites the figures are 14 percent, 30 percent, and 56 percent, respectively.

The State of Black Health: The life expectancy for blacks (68.3) is shorter than whites (74.4) by 6.1 years. The infant mortality rate for blacks is twice the white rate, 21.8 vs 11.4 deaths per 1000 live births, a phenomenon attributable to low birth-weight, pneumonia, and influenza, and effect of maternal disease upon the newborn. However, as Sullivan points out, "These averages obscure some apalling figures in some rural areas and inner cities of our country. For example, in Georgia (in the Southern US) today the average life expectancy of blacks is 8.4 years shorter than that for whites. In six rural counties in Georgia, the life expectancy for black males is only 49.6 to 51.5 years whereas the average life expectancy for white males in the same counties is from 59.5 to 69.6 years. In Kenya, one of the less developed and poorer countries of the world, the average life expectancy of the male population is 51.3 years, exceeding that in some rural counties in Georgia. In 1980 in 50 rural counties among Georgia's 159 counties, the infant mortality rate for blacks was higher than 30 per 1000 live births and in 16 counties the rate was higher than 43 per 1000. Similar rates are found in many rural areas and inner cities all over the United States" (Sullivan, 1983). A black mother is three times more likely to die of complications of pregnancy, labour and puerperium than a white mother. A black mother is more likely to have had very little or no prenatal care. In spite of the severe social and economic stresses on black families the incidence of recognised child abuse is similar for blacks and whites, around 11/1,000

The incidence and causes of head injury differ for blacks and whites, the black incidence for both inner-city and suburban blacks being twice that of whites (400 vs. 196/100,000). Interpersonal attacks were either the leading cause as in inner-city blacks (176/100,000) or the second most common (100/100,000) as in suburban blacks compared to the fourth most common cause for suburban whites 18/100,000) (Whitman et al, 1984). These head injury figures convey only the tip of the iceberg. For example, in 1979 murder was the leading cause of death to men 15 to 44 years of age in New York City and black men in this age group had " . . . a 1 in 20 chance of being murdered, a rate that is twice the odds of an American soldier being killed in combat during World War I " (Chicago Sun-Times, 1980) Homicide is the leading cause of years of life lost

Death Rates (per 100,000 Population) Homicide According to Race and Sex

	1960	1970	1979
Total	5.2	9.1	10.4
Black Males	44.9	82.1	71.3
White Males	3.9	7.3	10.1
Black Females	11.8	15.0	14.3
White Females	1.5	2.2	3.0

(Source : U S. Department of Health and Human Services Health, United States, 1982. DHSS publication No. (PHS) 83-1232 Washington D.C. : US Government Printing Office Dec. 1982)

for non-white men in the US. Age-adjusted death for homicide have climbed steadily in the past 20 years (see Table). As the table indicates, the homicide rates for black men are seven times that for white men, whose rates are lower than those for *black* women. Blacks have a higher death rate than whites for 13 of the 15 leading causes of death. Other significant differences are in diabetes, nephritis, septicemia and chronic liver disease and cirrhosis, where the death rate is twice that of whites. Deaths from cirrhosis increased by 50 percent for whites in the past 25 years whilst for blacks they increased 20 percent.

Let us look at some other health statistics. Regular dental health care is usually unaffordable (APH, 1982). In 1978, 82 percent of rural Southern blacks did not visit a dentist. For a white family a perfect set of teeth with the ability to flash a brilliant smile is a status symbol, and middle-class families, of either race, can spend nearly 1500 dollars, per child for orthodontia. Semi-annual dental visits for regular cleaning of teeth are routine for them, while dental care is out of reach for poor families, black or white.

When asked in 1978 to rate their overall health and "well being" as part of a Federal National Health Interview Survey, black females reported the lowest level of positive well-being of all groups 37 percent compared to 70 percent among white males. Access to health care is dependent on income level. This strongly affects families headed by black women as 71 percent of them live below the poverty level compared to 40 percent for white and 51 percents for Latinos. Government — sponsored programs — Medicare and Medicaid and tax subsidies for private health care have spent a trillion dollars

since 1965. Yet 34 million people remain without health insurance of any kind. Only 33 percent of people with income *below* the poverty level are covered by Medicaid, 27 percent have no health insurance of any kind. Uninsured blacks have a 42 percent lower Physician visit rate compared to whites, lower rates of elective surgery, are less likely to have a regular source of care, and have to travel further to obtain care It is estimated that one out of every four black adults suffers from hypertension, which develops earlier in blacks, is frequently more severe and results in higher mortality at a younger age. For black women of all ages the prevalence of hypertension is equal to or higher than that of black men.

Let us now turn our attention to the delivery of health care. Though forming 12 percent of the population, less than 2 percent of the faculties of medical schools are black. The percentage of black physicians in the country has increased only marginally from 2.1 percent in 1950 to 2.6 percent in 1980. Further, the propo ron of black medical graduates has decreased in the past four years from 793 out of 14,393 graduates (5.5 percent) in 1978 to 763 out of 15,985 (4.8 percent) in 1982. Six medical schools in the US have no black enrollment and in 75 (61 percent of all medical schools) the black enrollment is less than 5 percent. Black physicians, who have always faced difficulties in getting hospital privileges, are likely to face more difficulties in obtaining these privileges as hospital administrators try to keep hospitals financially solvent amidst cost-cutting measures initiated by government and private health insurance agencies. Black physicians tend to have a patient load which is predominantly poorer, sicker and less likely to bring in revenues to the hospital. Administrators are expected to try to eliminate the physicians who admit those kinds of patients — another example of economic racism (AM News, 1984).

Note that the percentage of black physicians has increased only marginally even with the positive impact of affirmative action programs. The changing and increasingly right-wing political turn which began in the late 70's can be further expected to decrease black enrollment. Additional factors that will contribute to the decrease are of equal importance. Black students in high school and college are victims of a pervasive inequality in education. A survey of high school students in the Chicago area (which contains 92 percent of all minority students in the metropolitan greater Chicago area) showed that 56 percent had seldom or never worked in a laboratory, the dropout rate at high school averaged 47.4 percent and about half of the graduating seniors from high school were deficient in the rigorous academic subjects that are required for medical school (Orfield, 1984). The cost of medical education rises each year; in 1984 the average medical student will owe a debt of 50,000 dollars Financial assistance is becoming increasingly short with a very grave impact on black students, 80 percent of whom come from families earning less than 25,000 dollars a year. At other levels of the health industry blacks become more commonly represented as one descends in the hierarchy. In the nursing sector blacks form 11·4 percent of the registered nurses, but 30 percent of the aides and orderlies.

The American Health Care Industry

Between 1950 and 1982 US health expenditures increased more than 25 fold. The proportion of the GNP accounted for by the health sector has increased from 4.4 to 10.5 percent (Ninzburg, 1984). In the past 10 years the number of people employed in the health sector has increased from 4.2 to 7.5 million. In sharp contrast to other sectors of the economy the health industry has expanded unaffected by any of the recessions of the past 30 years. Hospital room costs have gone up by 515 percent in the last 15 years and physician services by 311 percent. In 1981 hospital costs accounted for 41 cents of each dollar spent on health, physicians, services for 19, dentists services for 6, drugs 8, appliances 2. Other costs included nursing-home care 8, public health 3, research 2, new construction 3, and administration and others, 8. Health care costs average 1500 dollars per American of which dollars 906 come from private funds and 594 dollars from public programs.

For-profit hospital chains, a relatively new phenomenon, have grown and are expected to own 20 percent of all hospitals by 1990. In 1982 the largest chain, Hospital Corporation of America, owned 351 hospitals with 50,000 beds with revenues of 3.5 billion dollars, up 47 percent from the previous year. Humana, Inc, another chain, had 14 billion dollars in revenues with stocks worth 18 dollars per share in 1968 now worth 336 dollars (Starr, 1982). The for-profit hospitals, which are touted as being more cost-effective, have actually charged more per patient than their not-for-profit counterparts, whilst generating a very high net income for their owners (Relman, 1983). These chains are also moving into outpatient centres

called Emergicenters or Urgent Care Centers, which are open 12-16 hours a day, resemble the fast-food chains in their appearance, and have a potential market of between 2—5 billion dollars a year.

Health expenses in the US are met in two major ways, either by private health insurance or by government programs like Medicare and Medicaid. In 1974 the national average expenditure per non-white beneficiary was 57 percent lower than that for white (321 dollars vs 560 dollars). As we mentioned earlier, 34 million Americans are without any kind of health coverage, because they are too poor to afford private health insurance and earn more than the minimum requirements to qualify for government assistance.

The Indian Connection

The relationship between race and health care has obvious parallels for India, such as the hospitals based on class and the use of affirmative action in medical education, which if similar to the reservation system for Scheduled Castes and Tribes in India. Both in India and in the US there is yet another link, the Indian medical graduate (better known as F.M.G. or Foreign Medical Graduate), either in training or practising in the US. There are presently about 14,000 FMGs of Indian origin in the US, forming 10 percent of all FMGs and 3 percent of all physicians in the US. Note that there are *more* FMGs of Indian origin alone than the total number of black physicians in the US. A relatively large number of Indian doctors work in inner-city or county hospitals which serve the urban poor who are largely black. There is a decreasing number of Indians as one moves into the 10 most prestigious medical schools, the so-called Ivy League.

Black and Indian relations within the medical system have not been marred by overt conflicts, which is heartening considering the generally racist attitude of most Indian physicians. The federal government has backed affirmative action in admissions to medical schools though this backing has never been whole-hearted and can presently be said to be nonexistent. *White attitudes to affirmative action parallel those of caste Hindus in India. The very same arguments are used - selection should be on 'merit,' concern is expressed for lowered standards of medical care, and so on.*

The presence of large numbers of Indian doctors also strengthens relations between the Indian elite and the health care industry in the US. They have already begun to play a role in creating American-modeled hospitals in India like the Apollo hospitals in Madras and Hyderabad and the proposed Modi-Hospital Corporation of America hospital in New Delhi.

Conclusion

Black health statistics which improved in the 60s and 70s as a result of political changes stemming from the civil rights movement which stimulated government programme appear to have peaked and a reversal may have begun. The statistics of black health must be viewed in light of the moneys poured into health care in the past 30 years. In that unprecedented period of economic growth when real income doubled for most Americans, medicine was an "important ideological prop for the ruling class in the maintenance of the domestic tranquility and social stability needed for production and profit . . . health care has been used by the ruling class to cushion some of the most savage aspects of capitalist industrialization and forestall more radical working-class demands" (Himmelstein and Woolhandler, 1984).

But the stagflation of the seventies has heralded some fundamental changes in government policies. The Reagan adminstration has cut the health budget and reduced funding for education for poor and handicapped people by 20 percent (Stokes, 1981). Maternal and child health received 25 percent less federal money in 1982. A rise in the overall foetal death rate from 10.2 to 12.2 per 1000 from 1979 to 1981 may be the first indication of the effects of present cost-cutting measures (Pouissant, 1983).

The increase in the number of black people below the poverty line, the general low income of black people, the poor opportunities for advancement in employment are not features that are unique to the US. A recent publication from England (PSU, 1984) describes the black population as occupying the same "precarious and unattractive" position in society as in the 50s. The British National Health Service encourages a "ghettostyle" employment pattern with hospitals having British porters, Spanish cooks and West Indian domestic staff (Lancet, 1984). Doubtless the pattern can be documented in other white nations with regard to their racial minorities — Turkish in West Germany, Algerian in France, Maoris in New Zealand and Australia, leading to the conclusion that "Racism is not a 'mistake' or a 'failure' of this society — it is one of its great successes" (Cooper, 1983).

As the US changes to an hour-glass economy, a large section of the population will be left in low-paying dead-end jobs. In August 1984 the US

Census Bureau showed that the number of Americans living in poverty had risen to its highest level in 18 years. As a result of Reagan Administration tax policies, families earning less than 10,000 dollars annually suffered a net loss of dollars 400 or 4 percent of income, whereas those earning over 80,000 dollars gained 8,270 dollars or about 10 percent. This will further limit the number of blacks who can climb out of the poverty and degradation they are born into. Increasingly large US cities have a black majority population. The white exodus from the cities is matched by a loss in jobs in the manufacturing, wholesale, retail and service industries. In the past 10 years alone New York, Chicago, Philadelphia and Detroit have lost a million jobs with white unemployment levels staying relatively static whilst black unemployment levels have zoomed to nearly 55 percent for teenagers. These trends are likely to continue.

"Profit has made America what it is" is the proud slogan of American capitalism, which wishes to be known by its new, gleaming, dazzling, forprofit hospitals where the birth of a baby is celebrated by the parents with champagne. In their shadow lies the decay of overstrained public hospitals serving non-white citizens and bearing an uncanny resemblance to large municipal hospitals in India. Their burden will be greater than before as for profit hospitals both "cream" off capital and resources and leave to them unprofitable diseases and the care of minorities and poor people.

Voices of Silence

I'm nine years old
And I'll never die

One winter night
while I slept
and dreamt of
enchanted morns
piping hot jelebis
warm blankets
bright green kites
and blood red kurtas
a monstrous shroud
of sticky white fog
smothered me in a
terrifying embrace
endless, eternal.

In another time
and another place
I was nine years old
and did not die.

One August day
forty years ago
a mushroom cloud
rose from the earth
killed thousands
maimed millions
wiped out generations
embalmed me
for ever.

I'm nine years old
And I'll never die
I'll haunt the ghouls
who thrive
on the blood of
men, women and children
I'll echo the
sobs, screams and gasps
of toilers in pain
the eerie
silence
of premature death
And I'll never die.

I'll sit on your
shoulder for generations
I'll goad you, worry you
anger you,
and never let you go
until you create a world
where Bhopals
and Hiroshimas
are mere nightmares
of a distant past
never to recur.

Until then.

I'm nine years old
And I'll never die.

PEOPLE IN HEALTH CARE

No other profession enjoys the amount of adulation or gets its share of brick bats as does the medical profession. The problems of ill-health being what they are in our country, every discussion and debate on such issues revolves around the question of availability of doctors. This factor has assumed such a major importance that the doctor-population ratio has come to be accepted as a standard measurement of health services and indirectly of the health of a population. In this process the important contribution made by the other categories of health workers remains invisible only to come up when they strike work.

The central role doctors play in diagnosing and treating diseases is not merely confined to the provision of such services but extends to the entire field of health care including the right to define what constitutes disease and the right to treat it. The medical profession argues that if high quality services are to be made available and if 'purity' of medical practice is to be maintained it is essential that the profession retains complete control through registration and legislation. Further, the medical profession argues that diagnosing and prescribing are superior to all other skills and only those who possess such skills have the necessary authority to direct the course of health itself. That all such arguments merely form a facade for maintaining monopoly over a valuable commodity can be seen by looking at the way medical practice evolved into its present professional status.

The Beginnings of Medicine as a Profession

The emergence of the medical profession can be traced to 14th-15th century Europe which witnessed a class alliance between the upper middle class male 'regular' doctors and the feudal church leading to the ruthless extermination of other healers, mostly women, through well organised witch-hunts. Similarly, two centuries later in America the 'regulars' tried to gain monopoly over medical practice by attempting to pass state legislation in collusion with the emerging industrial and commercial bourgeoisie. Initially such attempts met with mass protests which culminated into a popular health movement. Unfortunately, the effort against legislation could not be sustained and the movement degenerated into a number of medical sects.

The 'regulars' attempt at cornering the market for their expertise was based on two factors. Firstly, the 'regulars' need to eliminate competition now arose as, for the first time, the practice of medicine was being viewed a full time economic activity. Secondly, if this activity was to bring in a substantial income, it was necessary to improve the image of the activity by giving it a professional status. As a mark of distinction the regulars adopted the Hippocratic oath and code of ethics as their standard. It is important to note that all this took place before medicine had attained any scientific aura or had developed any rational medical interventions. In fact, the regulars of that time practised what was known as heroic therapy which included blood-letting, purging and applying leeches among other such horriffic remedies.

With the support of the industrial and commercial bourgeoisie, it was just a matter of time before specific and effective interventions in the disease process developed which further consolidated the power the medical profession had gained through legislation and the physical extermination of other healers. It was this monopoly that shaped the form and content of medical care to its present form. The predominant hospital structure and the emergence of other categories of workers such as the nurses, laboratory, x-ray technicians, pharmacists and others has evolved and revolved around the functions that a doctor performed.

It was also not a mere accident that nursing emerged as a suitable profession for women or that it was subordinated to doctoring. By the time medical practice had become established as the domain of male regular doctors, women had been eliminated from health care for all practical purposes. The authority that doctors had in defining normality allowed them the power to advance pseudo-scientific theories and sexist arguments regarding the intellectual capabilities of women to prevent them from entering medical colleges. Women from the upper classes were increasingly being told to conserve their energies for the supreme function of being a woman, that is procreation, and were therefore forced to lead a sedentary life. For the women from this class who did not or could not marry, life had little option. Apart from teaching there was hardly any respectable 'genteel', non-

industrial occupation which would be socially acceptable and at the same time provide a certain level of economic independence. The goal of Florence Nightingale, the 19th century reformer was to create a paid job in health care for women. To make it acceptable to doctors Nightingale demonstrated in the battle field of the Crimean war that nursing would remain subordinate to doctoring and her attempt to make the occupation acceptable to women was to draw analogies between nursing and housework. The doctor-nurse relationship was projected as a husband-wife interaction and nursing was stated to be 'natural' to women, as it coincided with what was considered to be her natural biolgical function. Since Nightingale's effort was to create a job for the women in health care she made it quite clear that it would in no way question the supremacy of doctors or the subordinate position of nursing. Feminist historians however question the acceptance of nursing as a *natural* sexual division of labour. By taking patriarchy as an analytical category they have tried to argue that what is generally considered a natural sexual division of labour is in reality a *social* division of labour which designates men to be superior to women in all social interactions, concerning men and women.

The heritage handed down to the nursing occupation by Nightingale and other reformers has left its indelible mark on the issues identified by the nursing profession in the later years. Nurses have taken up issues related to registration, professional status and for a certain degree of organisational autonomy. But at no time has the nursing profession questioned its subordinate position. In fact one of the barriers for expanding the nurses role to a nurse-practitioner came from the nurses association in the US, who were reluctant to accept the responsibility for diagnosing and treating.

In India one could say that the health care system expanded only after independence. Although on the whole its evolution was similar to the development that took place in the West, there were certain dissimilarities. For instance, even as far back as 1883 several universities in India began to accept women as medical students. The Bhore committee in its recommendations at 1946 stated that at least 20-30 percent of seats in medical colleges should be reserved for women students. The change in attitude of the profession towards women students was perhaps related to the constraints placed by the purdah system on women in general which prevented the male medical profession's entry into areas such as maternal and child health. The post independent years have seen attmepts to provide medical services through an alternative health care structure by establishing primary health centres and subcentres to cover rural populations. But throughout all these developments adequate care was taken to ensure that the monopoly exercised by doctors would be maintained and remain unquestioned

The Bhore committee stated categorically that only the physicians trained in allopathy, should be called doctors and the doctor was to be the unquestioned leader of the medical team whether it was in the operating room or in the primary health centre. It emphasised the training of one level of doctors and recommended the abolition of the Licenciate course. Without analysing the class background of the doctors or their class interests the members of the committee hoped that training sufficient number of doctors would ensure that they would opt for the villages. That the committee was not sufficiently interested in the other categories of health personnel can be seen by the number of pages devoted in their report on the training of doctors and all other categories of workers. Later committees too have emphasised the role of doctors at the cost of neglecting all other health personnel. The need to train a 'lower' category of practitioner is discussed time and again but is always rejected on the plea that it would lead to quackery. At the same time when the suggestions that a 'lower' level of nurse be trained was made by the nursing council it was greeted as the most feasible solution given the low resources available in the country. Similarly when the Shrivastav committee made its recommendation in 1975 for training village level workers, it also allayed the fears of the medical profession by stating that since the role of these functionaries was educational, their curative skills would be limited to just a few remedies for simple day to day illnesses.

The end result of all such actions has been to create a structure which is rigidly hierarchical reflecting the class structure in the broader society. Just the way the economic status or caste of a person largely influences his/her future position in any socio-economic activity, in medical practice too these factors very often determined which level of hierarchy s/he will occupy in the health structure. This streamlining into 'suitable' rung in the hierarchy is generally mediated through the person's performance in and access to education. For instance, the three categories of nursing personnel we have in India that is the B.Sc. nurse, the Registered

Nurse Registered Midwife (RNRM) and the Auxiliary Nurse Midwife (ANM) required different levels of educational qualifications to enter into their respective training schools. This determines the class that will be predominant in each of these categories which is further consolidated by the differential salary structure and status afforded to these three categories in the nursing profession.

Since medical care is a valuable commodity and the right to provide it has been appropriated by doctors, all other categories of health workers and the functions they perform remain subordinate to that of doctors. This monopoly is often carried to ridiculous lengths, such as the prohibition on nurses to start an intravenous drip or give an intravenous injection.

Reports discussing the problems of health personnel have also mostly focused on the problems faced by doctors. One hears repeatedly that doctors have to face innumerable problems such as lack of educational facilities for their children, lack of 'entertainment' in the village and less opportunities for professional growth; and that unless these facilities are provided it would be unrealistic to expect doctors to work in the villages. But these 'problems' really pale in significance if one considers the difficulties an ANM faces during the course of her work.

Nurses : Problems They Face

The problem nurses face needs to be dealt with separately. Their contribution has been mostly towards the care of patients, although they perform important technical tasks too. The rural health services rest largely on the functioning of female health workers and their non-performance could very well paralyse the entire rural health network. Yet their status within the structure of health services has remained one of subordination. Attempts in the past to improve the status and image of nursing has very often been limited to increasing the content of the curricula or the technical content of their work. But this only ends up in reemphasising the fact that 'caring' as a function cannot be held on par with that of diagnosing and prescribing.

As women, nurses have an added problem of sexual harassment which they have to continuously face both within and outside their work situation. One reads of newspaper reports of nurses who are molested, who commit suicide because of sexual abuse or are murdered for their unwillingness to be casual sexual partner. One could hazard a guess that the women health workers in rural areas are probably exposed to such problems to a greater extent. This is not because the rural males are different from their urban counterparts but rather the situation that the nurses are in makes them more vulnerable. Isolated as they are in remote villages, with little support from other health workers these women health workers suffer in silence out of sheer economic necessity to retain their jobs. This could also be the reason why such incidents are under-reported.

Although this problem has been recognised as a major constraint there has been no systematic effort to document these incidents or evolve support systems to tackle such problems. Addition of self defense into all nursing curricula as a skill to be developed by nursing students could perhaps be one such way. But a more realistic solution would only emerge if nurses' unions take up this issue seriously to launch a struggle to make their work place safe. Indeed for such struggles to succeed they will have to become part of much larger struggle of all women. The top two categories of nursing personnel are generally better placed to form unions as they work in hospitals and are physically proximate. The ANMs on the other hand who work mostly in the PHCs and subcentres have little opportunity to come together to raise their collective demand.

The work force employed in the hospital industry is similar yet distinct from that employed in other industries. The distinction lies firstly in the fact that these functionaries work on raw materials (patients) to produce a non-quantifiable product 'health'. Secondly, the physicians and sometimes the nurses who occupy the higher level of hierarchy view themselves as professionals rather than as workers. This often contrasts with the attitude of non-medical hospital workers who view their activity merely as a job. But the situation is changing now. Doctors, nurses and other 'professional' health workers are getting unionised and demanding more and more job benefits, fixed duty hours and overtime pay, in the process assuming the form of wage earners. But even when such issues are taken up they try to use their 'professional' status to push their point. For instance, in the recent strike by the interns from medical colleges in Delhi, a placard was used with the legend 'Doctors lathi charged! What next!'

Although the demands of the 'professional' categories are similar to that of non-medical hospital

workers there is little attempt to identify these issues as common issues and to unionising on the basis of their identity as workers.

One of the limitations of this perspective as well as the whole issue on 'People in Health Care' is that we have concentrated on health workers functioning as part of the allopathic system of medicine. We really know very little about health workers belonging to other systems of medicine in India, in terms of their role and status. Further even among the workers in the allopathic system very little information is available about non-physician health workers.

Finally, a word about the people on whom the 'people in health care' work upon. As patients they are the most powerless in the interaction that takes place in a health care set up. They are neither in a position to direct the course of their treatment nor can they demand a social accountability from health personnel. The self-help movement in the west has been a reaction to such powerlessness. It remains to be seen whether the concept of self-help can ever become a viable alternative to the present system as it exists today.

NEW DELHI 110017

In this issue :

Sujit K. Das explores the much debated subject of the class location of doctors and queries the stereotypical definition of medical care as a commodity. Rajkumari Narang looks at various studies in anaemia to illustrate her contention that the choice and treatment of problems in medical research is rarely governed by factors such as people's needs. Imrana Quadeer examines the impact of the rural social and economic realities on the Community Health Worker's Scheme. Sumathi Nair takes a closer look at four Community Health Projects and asks what their relevance is today. The issue also carries two articles outside the theme of People in Health Care. Ekbal reviews the marxist critiques of the Ilichian School and Amalendu Das throws light on dust hazards faced by coal miners.

SUBSCRIPTION RENEWALS

Is this your last subscribed issue ? A prompt renewal from you will ensure that your copy of Vol. II No. 3 on 'Systems of Medicine' is mailed directly from the Press. Book your copies by renewing your subscription now !

Our subscription rates remain :

For individuals — — Rs. 20/- (four issues)
For institutions — — Rs. 30/- (four issues)
Foreign subscriptions : US $20 for US, Europe and Japan
US $15 for all other countries
(special rates for developing countries)
Single copy : Rs. 6/-

DDs, cheques to be made out to SOCIALIST HEALTH REVIEW, BOMBAY.
Please write your full name and correct address legibly. And please don't forget to add Rs. 5/- *on outstation cheques !*

SHR BACK NUMBERS

We have in stock the following issues :

Vol I : No. 2 - - Women and Health (Reprinted edition)
No. 3 - - Work and Health (Limited stock)
No. 4 - - Politics of Population Control
Vol II No. I - - Imperialism and Health (limited stock)

Vol I No. 1 is out of print. We are planning to reprint it, if we get more than 200 orders - - at a cost of Rs. 10 each. We can get the entire issue photocopied at Rs. 25/- If you wish to obtain individual copies of any of the other issues, please send us for Vol I Rs. 5/- per copy plus postage of one rupee (ordinary post). for Vol II No. 1 send Rs. 6/- plus postage.

DOCTORS IN HEALTH CARE
Their Role and Class Location

sujit k das

Doctors have played a central role in health care services. In India medicine has enjoyed both state and popular support since the independence. State health services expanded rapidly as did the number of doctors. Many of these doctors went into private practice or migrated to other countries and others into the state health services. This article explores the much debated subject of the class location of the medical profession. Is the general practitioner a productive labourer or a capitalist ? Does the doctor in service belong to the working class ? The author draws attention to the effect of the state sector on the medical profession and traces the growing agitational movements and organisation of state doctors in the country, with special emphasis on West Bengal. Against this backdrop he queries the stereotypical definition of medical care as a commodity.

Doctors are the most important people in health care. Even the official expert group on health, after unrestrained criticism of the doctor-dependence of our health system, concedes "Moreover, the doctor as the leader of the team can play an important role and influence the values and the quality of caring among the whole staff if he shows these concerns himself" (HFA, 1981). Radical critiques on health care call for reversal of the doctor-dependence of the health system but nevertheless wish for a change towards socialisation and social orientation of the medical profession. Popularly, doctors are looked upon as next to gods since they deal with life and death and no wonder doctors are often beaten up when a patient dies or there is allegation of negligence on the part of the doctor. The popular view offers the medical profession the key position in health care; expects it to protect the health of the people; regards it as the greatest depository of knowledge and wisdom regarding health; believes that the weakness of the health care service is due to lack of adequate number of doctors. From the Presidents of India down to the Taluk functionaries they have all been exhorting the medical profession to be patriotic enough to go to the remote villages and stay there to serve the under-privileged rural people.

Surprisingly few attempts have been made to investigate, analyse and understand the medical profession in the perspective of concrete reality. Despite its crucial role, the medical profession is commonly assessed on the basis of subjectivism. Just as the modern medicine had been borrowed from the west, the Indian critiques of the Indian medical profession appear, more often than not, to have been borrowed from the western radicals. The profession had hardly been looked into as what it is, but often analysed on the basis of what it should be.

Development of the Profession

In India the art and practice of healing devolved on to a group of socially engaged men, and several systems of medicine developed and have survived till to-day. Each system was somewhat well-developed corpus of knowledge and its practice had traditionally been taken up by successive generations. Following the changes in the relations of production and exchange, independent practitioners emerged. Later, systems of modern scientific medicine (allopathy) and Homeopathy came from the west and took roots.

In the 19th century, modern medicine had little to offer. The 20th century, heralded the appearance and development of a scientific basis and since the thirties, appearance of chemotherapy and improved surgical techniques created a surge of interest in, and attraction towards, modern medicine owing to its dramatic life-saving achievements. Popular attraction received a further acceleration around and after the second world war as a result of the invention of newer wonder drugs and technology. The practice of modern medicine, likewise, earned a heightened respectability and soon rapidly emerged as a profitable livelihood.

Demands for the expansion of the hospital services have been raised from all corners. The situation is a parallel of what prevailed during the expansion of hospital services in the National Health Service (NHS) of UK. "For the politician, it might be assumed, there could be no better advertisement than a shining new hospital: a visible symbol of his or her commitment to improving the peoples'

health. For the doctors, new hospitals meant the opportunity to practise what is considered to be higher quality medicine. For the consumer, in turn, new hospitals surely meant better services with higher standards of treatment (Klien, 1984). No wonder therefore, in a market economy, almost all aspiring doctors moved towards the practice of curative medicine with its life-saving and relief-producing implements. Illiffe has put it succinctly, "Just as abortion would be a sacrament if men became pregnant, so health professionals would stampede into preventive work if prevention could be made into a marketable commodity" (Illiffe, 1983).

Introduction of welfare activity by the state saw the expansion of state health care service and the number of health personnel increased rapidly (Table I). Later, indigenous systems and homoeopathy, for reasons not discussed here, also received state patronage.

Table I

Year	No. of Med. Colleges	Students admitted	Qualified
50-51	28	2675	1557
60-61	60	5874	3387

These doctors opted for private practice or other employment or post-graduate education for specialisation, or migration to foreign countries. For the last few years more than 2000 doctors have been settling abroad annually. There is no available data to indicate the number of doctors engaged in each category but the distribution follows the market situation and economic compulsion. Old pattern of general practice recruits less and less. Number of women doctors has been steadily increasing since 1976-1977 and they generally settle towards certain culturally chosen occupations e.g. gynaecology and obstetrics, pediatrics, pathology, plastic surgery, anaesthesiology, non-clinical disciplines in medical colleges and also dental surgery. Most of the women opt for employment and independent women private practitioners prefer G & O and Pediatrics. Unemployment is a late development (Table II).

Class and the Medical Profession

Private Practice and General Practice

In West Bengal, approximately 70 percent doctors are engaged in private practice. They include independent practitioners, Insurance Medical Practitioners of ESI (M.B.) Scheme, part time practitioners of the state and private sector employees. The General practice has been changing with changing social relations, scientific developments and cultural attitudes. In earlier times, the general practitioners (GP) could not demand any consultation fee and had to distribute drugs to his clients. He then used to incorporate what he considered to be his due consultation fee, within the price of the drug. As a result, the consumption of non-essential drugs and compounded drugs was high. Also the actual price of a compounded drug is difficult to check and verify. Later, consultation fee has gradually been introduced and has received public acceptance, resulting in the development of a class of GPs who are only prescribers.

Indian society has a long tradition of voluntary efforts for charitable medical care to the community. In fact, a good number of clinics and hospitals had been established through philanthropic endeavours. In order to earn and maintain 'nobility', the price doctors had to pay was to attend to emergency patients, give free 'service' to a few indigent patients and offer honorary service in the voluntary institutions. Besides respect, speedy recognition and fame, this attachment to charitable institutions used to bring other material returns. The doctor used to test the emerging therapeutic techniques on poor patients without informed consent and without risk and later employ the technique thus perfected, in cases of paying clientele in the private practice. Actually, the situtation is so advantageous that there is serious competition among the contending doctors to secure honorary employment in the charitable medical establishments. A sort of corrupt practice was also rampant where the patients had to pay the honorary doctor in order to avail of the free hospital service. This malpractice has now been almost eliminated in West Bengal due to higher level of consciousness of the people, but is still in vogue in many other states.

The GP therefore, acts as a retailer of drugs; sells his skilled labour designated as 'service' to

individual buyers; and it may further be argued that he employs his knowledge and skill as capital and sells the product of his own labour in the market as commodity. Is he a productive labourer or capitalist? Karl Marx, in his inquiry into the social status of independent handicraftsmen and peasants as well as that of producers of non-material production e.g. artists, actors, teachers physicians, etc., said "It is possible that these producers, working with their own means of production, not only reproduce their labour power but create surplus value, while their position enables them to appropriate for themselves their own surplus-labour. ..... And here we come up against a peculiarity that is characteristic of a society in which one definite mode of production predominates, even though not all productive relations have been subordinated to it. ... The means of production become capital only in so far as they have become seperated from labourer and confront labour as an independent power. But in the case referred to the producer – the labourer is the possessor, the owner, of his means of production. They are therefore not capital, any more than in relation to them he is a wage-labourer" (Marx). The GP is actually engaged in a precapitalist mode of production, but nevertheless produces commodity of use value and sells it for exchange value. Our much maligned GP is not altogether a demon or blood sucker. He is just a small commodity producer who still renders essential service which the state is unable to provide for. A close study of the GP will reveal how the western medicine took roots here, changed the health culture and in the process changed its own.

Speed of expansion of the market of private practice has lately been thwarted and is gradually being squeezed for several reasons. Increase in the purchasing capacity of the people cannot keep pace with the increase in the number of doctors thrown into the market. Secondly, expansion of the state sector in medical care has been impressive and concentrated in the urban areas and these are totally free or heavily subsidised. Socially dominant classes who can afford to purchase medical care, have been able to capture the largest share of the free/subsidised state service. As a result, private sector medicare did not develop to the expected level. Thirdly, private practice has a latent period to reach profitability. Lately, increasing numbers from the lower income groups have been recruited in the medical profession, who cannot afford to sustain this latent period. All these have resulted in increasing trend towards employment and migration abroad, unemployment and underemployment.

Doctor-in-Service

Expansion of organised medical care service through state, public undertakings, ESI, big private industry and voluntary organisations has resulted in a marked increase in the number of doctors in employment. Though private medical practitioners still constitute about 3/4th of the medical profession, the doctors-in-service attract the major, if not entire, attention in any debate on health care owing to the fact that the organised sector is the trend-setter and almost always features in planning and debate In this context, the present discussion dwells largely on the doctors-in-service among the practitioners of modern medicine. However, no discussion on the medical profession or for that matter, medical care is compreshensive unless it also includes private practitioners of modern medicine and of the other systems.

The non-practising employed doctor is actually a wage earner destined to identify himself with the aspirations of similar wage-workers of the so-called white-collar category. Though the 'noble profession' ideology provides an excellent instrument for the private practitioners to maximise profit in their trade, it has ironically proved to be a constraint in the way of fulfilling his aspirations. Because of the stigma of 'noble profession', he cannot claim fixed duty hours; cannot claim 'overtime' i.e. extra remuneration for extra work; cannot employ 'red-tapism' in his daily work-load; cannot even utilise his earned leave to escape from the drudgery of frequent emergency duties. He is further handicapped in regard to democratic rights so much so that unionisation of doctors is frowned upon by the society; agitative action is taboo; call for strike in hospitals is taken to be sheer blasphemy. On top of it, the doctor has little hold in the administration of medical care and in the matters of policy-making, programming and power hierarchy, the doctor is placed in a lower position subordinate to the generalist administrator But more about this later.

Do they, then, belong to the working class? The question has never been raised or debated. On this issue, the dogmatic marxists adhere to Reductionist ideology. "Reductionism involves a version of historical materialism which presents all social phenomena as 'reducible' to, or explicable in terms of, the 'economic base'. Thus political struggles or social ideologies are explained as manifestations or 'reflections' of economic forces. In this presentation marxism is reduced to asset of

relatively simple and universal 'laws'. ..... Such a position is guilty of 'essentialism', that is of seeing the economy as embodying the essence of all social phenomena which are then simply expressed or made manifest in the social world" (Hunt, 1978). This methodology necessarily attempts to define classes at the economic level and attaches little importance to the forces operating at the political and ideological level Working class is differentiated by the difference between productive and unproductive labour. Mere wage-earning or labour-selling do not provide entitlement for entry into the working class. "The working class in the capitalist mode of production is that which performs the productive labour in that mode of production. ..... Although every worker is a wage-earner, every wage-earner is certainly not a worker, for not every wage-earner is engaged in productive labour" (Poulantzas, 1975). While in cases of white-collar wage-workers of the industry, transport and mercantile enterprises, Marx concludes that they are productive labourers, the physicians-actors-teachers etc. are also productive labourers. He observes, when they sell their labour power (manual or mental) in a capitalist establishment which appropriates their surplus labour and makes a profit by selling the products as commodities. But he adds, "All these manifestations of capitalist production in this sphere are so insignificant compared with the totality of production that they can be left entirely out of account" (Marx, 1978).

Technology, capitalist organisation of production and productive forces are much more developed now than at Marx's time, though the development of medical care service as a sector of capitalist industry is still rudimentary in India. The new working class of advanced capitalism — the technicians, engineers, scientists etc. — is held, by Serge Mallet, not only to be revolutionary but the 'avant-garde' of the revolutionary socialist movement (Mallet, 1975). Services have long been developed into profit making industry in the developed countries.

Here in India, doctors as wage-earners are now commonplace. To what class do they belong? The established left still subscribes to the liberal concept of health care and therefore, has yet to face this question. The progressive view, however, is confusing, to say the least. "The capitalist can organise the production of surplus value through the provision of health care and can realise higher profits in this service industry. It is immaterial whether the surplus value is realised directly through the productive activities in the clinics and hospitals owned by the Capitalist or indirectly, through the provision of health care by the State to maintain or increase the productive capacity of the labour." (Jesani and Prakash, 1984). Such an assertion is based on dubious premises that medical service has developed into an industry; that the State also acts as a productive enterprise; and that State Health Care Service is an organised investment by the capitalist class on the industrial productive labour.

What then is the status of the producers of 'health care'? The above assertion automatically places the employed doctors into the category of the working class. But alas, the entire medical profession carries, in the radical viewpoint, the same class background as the bourgeoisie and performs its predestined social task of legitimising-strengthening and maintaining the bourgeois medicine. Why this confusion? "The mere quantum of the so-called marxist analysis of health, done in the West has so impressed us that we have literally lifted their formulations and transplanted them on the Indian scene, without even thinking whether they are applicable. Further, in our hurry to fill in the gaps in our knowledge, we have concentrated on theory of health and medicine. That theory, however has been sought by filling the accepted theoretical constructs with Indian data and developments rather than beginning with health and health services itself to test the assumptions as well as the theoretical constructs" (Quadeer, 1984). In other words, in order to understand and analyse its status, role, trend and potential in health care, we have to make an actual study of the medical profession in its concrete reality.

Professionalism

"Professionalism within health care is based on the idea of 'service' and on the practice of trade. It is a market concept expressed in the relationship between a customer (the patient), a tradesman (the professional) and assorted suppliers (the drug industry, other superior professionals). Trade secrets are necessary for the maintenance of the market relationship, and permit professionals to define themselves as special, and beyond the control of those ignorant of these 'trade secrets'. The autonomy of health professionals — particularly doctors rest on the range of their trade secrets" (Illiffe 1983). With this conception it follows that professionalism could be curbed or even abolished with the

abolition of market economy i. e. private trade or commodity market in health care. This appears to be another instance of radical presumption. Professionalism is not a creed peculiar to the medical profession nor to the bourgeois ideology. Professionalism not only regins in private medical trade but also exists among the employed non-practising professionals, among the medical teachers of non-clinical disciplines and among the doctors engaged in public health work.

Professionalism exists in pre-capitalist economy and continues in the post-revolutionary societies where the ownership of the means of production has undergone a change and private trade almost abolished. In a round table discussion on private medical practice organised by WHO, it has been revealed that private practice, in certain forms exists and is developing in the socialist countries (Roemer, 1984). Medical co-operatives are springing up where state-employed doctors are allowed to spend upto two hours a day and are entitled to a 50 percent share of the payment received from the patients in cash for the services rendered. Even in China, barefoot doctors who are essentially paramedics, are allowed part-time private practice. A common practice developing in these countries is that of giving gifts to doctors in hospitals and often the gifts are relatively large amounts of money. All this is done to ensure better quality of service (which is by no means certain). How is the quality of service to be determined ? How are measures and gradations to be made ? There is as yet no acceptable indicator or scale. Hence, quality will be determined differently by different social ideologies and health cultures, and the latter are manipulated by professionalism. Specialisation and mystification are only other facets or instruments of professionalism utilised to maximise the price of medical service in private practice.

Specialisation, however, is not an exclusive exploitative imposition. It is also an integral part of social division of labour, not only unavoidable but necessary in any social formation including the one based on non-exploitative mode of production. What is relevant is not to confuse social division of labour with capitals' division of labour. In an analysis of modern chemical industry in UK Nichols and Beynon have shown that though technical division of labour is a must in any industry in any mode of production, in the capitalist mode the technical imperatives are subordinated to political imperatives and technology exists to serve and augment capital. "Certainly in any mode of production, given the existence of specialised training, some men will be more technically competent to solve certain problems than others This is so obvious as to hardly require stating. But something else which should also be obvious is often ignored. For concern with the technical structure of complexes like Riverside (the factory site) can also too easily obscure the fact that they are not even designed to make chemicals, but to make chemicals for profit The reality is that their division of labour is capital's division of labour ..... (Nichols and Benyon, 1977) Professionalism, also, could make its contributions in the struggle against the ruling class and the state. The history of the development of health care service in Great Britain has shown that the professionalism of the doctors thwarted, at different stages, the attempts of the state to reduce or withdraw the medical benefits demanded by the people. Here in India also, professionalism often reinforces the demands of the people for the egalitarian distribution of medical services against the discriminatory practice of the state.

What do we expect from the doctors? Here, the bourgeois, left, radical and popular views converge and appear as if grossly influenced by the ideology of professionalism. A doctor should render utmost efforts irrespective of the socio-economic status of the patient; should always ungrudgingly serve emergency patients without consideration to his own convenience; should always be guided by the code of ethics formulated by the profession; should act as a friend-philosopher-guide to the patient; should exude hope and confidence in his conduct etc. etc. Concomitantly, the community accorded certain privileges to the profession. The doctor knows best; he should not be questioned; he has the unchallengeable right to handle and manipulate the patient's body; his good faith is taken for granted even in cases of the patient's death and disability.

What do the doctors think about their own role expectation? In a large study in two medical college hospitals in Tamilnadu, Venkatratnam revealed that the doctors' understanding of their role expectation is a composite of their own individual perception, occupational compulsions and organisational (professional and institutional) principles (Venkatraman, 1979). Role expectation comprises of professional, academic, research, managerial and social. Many interesting facts and controversial issues regarding doctors' responsibility towards patients, role towards other health workers, requirements of teaching-training-research, level of

communication with patients, social responsibility and so on have been revealed in the above study and these should be analysed before rushing to issuing sermons on doctors' role expectation. Peculiarly, the ICMR-ICSSR report, while castigating the profession for its negative attitude towards preventive and promotive health care recommends for their 'alternative model' of health care service that "the doctors will still continue to play an important role in the new health care system. But this will not be over-dominating and will be confined more and more to the curative aspects of the referral and specialized services for which they are trained" (HFA 1981).

Universally, the understanding of role expectation of the doctors suffers from an idealistic approach. All expect the doctor to be humane, shorn of commercial urge, dedicated to patient's welfare, imbibed with principles of social justice etc etc. No one asks why the doctor should follow such a model or what objective conditions may compel him to do so? Or for that matter, what objective conditions persuade the doctor to do as he does?

Perception of role performance differs between the professionals and the consumers for obvious reasons. Confusing and paradoxical situations prevail. While the State hospitals and the doctors are almost always on the dock by the consumers and mass media for the severe shortcomings in role performance, the very same hospitals and the professionals are very much in demand for their high quality and indispensible medical service. True, the service is attractive because it is free. But even amongst affluent consumers the notion prevails that the hospital doctors are more skillful, knowledgeable and equipped. Generally, the doctors' notion on role performance is that they do their best under the given circumstances and they could do more if they have a free hand in the administration which is responsible for the constraints. The factors underlying these confusions and paradoxes are being unravelled by the growing momentum of the organised movement of the doctors.

Doctor's Organisations and Agitations : West Bengal

Medical practitioners got themselves organised under Indian Medical Association in the thirties. Later, practitioners of each speciality discipline built up separate associations. The basis of these associations is professionalism, academic and pseudo-academic. It should be mentioned that non-clinical and even public health disciplines organised their own associations. But the associations could not cope with the task of tackling the emerging aspirations of the employed doctors. In fact, a contradiction developed between them. Ironically, the bone of contention was economic as well as ideological. The ideology of professionalism appeared to be a drawback for the service-doctors. The pay packet of service was unattractive not only in comparison with the income in private practice but also compared unfavourably with that of the similar category of government officers, for instance the civil service, or the engineering service. This situation had been a hangover from the British days when doctor's pay packet was deliberately kept low with the understanding that they would make it up with the earning from private practice, a privilege then enjoyed by all service-doctors. Later, with the expansion of the state sector, more and more doctors had been employed on non-practising basis but this principle of wage policy did not change.

In matters of job requirement, job perquisites and job satisfaction, there was nothing glamourous to look forward to. Duty hours was virtually feudal - a doctor was 'on call' for 24 hours a day for emergency need and seven days a week; almost all health centres in the rural areas were manned by one doctor in each; there was no ceiling on the number of patients one had to attend daily; a rural medical officer, in addition to his clinical duties, was entrusted with the tasks of family planning, MCH, School Health, Immunisation, Epidemic Control Administration and what not. System of recognition and appreciation of good and dedicated service was absent. Avenues for higher education, promotion, research, or even a transfer to a better post after a scheduled period of service, were severely limited. Because of longer period of training to acquire qualification, a doctor usually enters service at a later period compared to others and consequently is entitled to a lower pension and lesser amount in the retirement benefits.

The state hospitals were always understaffed and underequipped and hence, the scope of practicing what the doctor was trained for, was thereby limited. On top of these, the health administration was run by the generalist administrators. These people had no career attachment to the health department; were not answerable for failure or mismanagement; had no inclination to learn the problems of the health care service as well as of the employees. The doctor had no voice in health planning, hospital service development and technical development. The autonomy enjoyed by the profession

in regard to clinical practice in the NHS of UK was not even partly granted to the doctors here. On the other hand, the political authorities found it convenient to put the blame on doctors and other health workers for all their failures, misdeeds and incompetence in the health sector. Consequently, doctors and the health workers, as they were the ones, at the counter, had to suffer the burden of public wrath in the form of physical assault, humiliation, abuse and so on.

What did the doctors do to overcome these adversities? It is worth while to note that the state service was last in the list of priorities of a new medical graduate. The order being private practice, specialisation, migration abroad and if all fail — then he opts for service. Lately, because of competition, the options have shrank greatly and large numbers are now competing among themselves for limited state service; doctors from Orissa, Assam, Bihar, Bangladesh are now applicants to the West Bengal State Service.

In this situation how have the service-doctors reacted ? Quality has been the first victim and expectedly so. No matter whether 50 or 500 attend the outpatients clinic the experienced doctor manages to tackle them within 3 hours or so. In a 100-bed hospital, 200 patients stay indoor regularly but the same number of doctors and health workers treat them without spending any additional time in the hospital. The next escape route is private practice — both authorised and unauthorised. In west Bengal except in the case of clinical teachers of the majoritv of medical colleges and doctors in the district and subdivisional hospitals, private practice is not allowed. In fact, 7/8th of the State doctors are non-practising. The States of Orissa, Andhra, Maharashtra, Punjab, Hariana and others have either entirely or partly non-practising state service. Some other states have indicated that they will too follow suit. The entire Union government and the public undertakings sector is non-practising. Expectedly, most doctors aspire for the limited practising privilege of the service and in the non-practising sector, unauthorised private practice is growing wherever there is scope and opportunity.

The question of the alleged reluctance of the doctors to serve in the rural institutions should be understood and analysed with this background in mind. Concerned people have swallowed the government propaganda that because of such reluctance on the part of the doctors, the government despite earnest efforts and liberal financial allocation, fails to provide medical care to the rural people. By absorbing this propaganda uncritically, the health activists on the one hand, unwittingly agree with the government that medical care is synonymous with the presence of a doctor, fall in another trap that provides for offering barefoot doctors Homoeopaths-Ayurveds and simple home remedies for the villagers in the garb of tradition, indigenous culture and community medicine. The fact is otherwise. It is deliberate government policy to keep the service conditions of the rural medical officers unfavourable with a view to discourage the doctors from taking up rural postings; and in this attempt, one must admit, the government has been successful to the exent that even the occasional few socially conscious people-oriented young doctors, after a stint of rural service, try their utmost to move to the urban area or quit. ' The Siddhartha Roy Congress government's regulation of 1974 stipulated that physicians with specialist degrees would enjoy a higher pay, a special allowance and would be exempt from rural postings. It was only natural that young doctors went in for specialisation just for the sake of avoiding rural posting, if not for higher emoluments. The Left Front government has not felt it necessary to change the regulation" (The Statesman, 1985). This policy in fact, induced even those doctors, who had already settled in the rural areas, to move for any type of specialisation and settle in urban areas. Does it show reluctance on the part of the doctors or that of the government? Lately, the Marxist Left Front government in West Bengal introduced against the protest of the medical profession, a short term three year medical course to train up doctors who would fill up the rural vacancies. Next year, the junior doctors in the State launched agitation for jobs in the State service and demanded that all rural posts be immediately filled up by currently eligible 3000 unemployed young medical graduates. Under public pressure, the Left Front publicly declared that there were no such vacancies and they were unable to provide jobs, not even in the rural areas. The short-term medical course had to be wound up in any case, the discrimination against the rural medical officers persists. No one, of course, raises the question why doctors, of all people, must go and serve the villagers who are ignored in respect of all other consumer goods. It must be understood that the recent organised demand of the junior doctors for rural appointment is not due to any sudden surge of patriotism but simply due to pressure of unemployment.

In course of time, however, the consoling compensation through private practice turned out to be insufficient. Service-doctors and junior doctors ventured to organise their own bodies on trade union basis to voice their grievances which did not find deserving place in the earlier professional bodies like IMA which was dominated by private practitioners. In 1973, junior doctors launched a movement in West Bengal demanding better pay and service conditions, and better provisions in the State hospitals They had to go on strike and come out partially successful by obtaining pay hikes. In 1974, the State doctors (in alliance with the State engineers) resorted to strike for 41 days but maintaining the emergency services. Their demands were not only economic but encroached on the political and ideological level. They demanded exclusive executive power for the scientists, technologists and professionals in the scientific and technical departments of the State administration which were the preserve of the generalists, and parity in pay scale with the Indian Administrative Service (IAS). This agitation generated intense debate throughout the country and the issue has not yet been settled. The West Bengal government ultimately made a few concessions but unfortunately, with the subsequent imposition of Emergency in the country, the terms of the agreement were not implimented, leaders were sacked and doctors terrorised. The fall out of this agitation was visible elsewhere; the pay scale of the doctors in the Union government and public undertakings were soon revised upwards to bring it on par with that of the IAS at the lower level.

This agitation made a breakthrough on several grounds. People saw to their surprise that renowned professors and principals of the medical colleges, eminent specialists and senior engineers holding high ranks in the state service, walking in processions, squatting on the pavements and holding street-corner meetings. It then struck them as a novelty that the 'noble' doctors could resort to agitative ways that befit only common workers. Doctors, it was stressed, had no right to jeopordise the well being of the patients by striking. This agitation, perhaps for the first time, focussed people's attention on the affairs of the medical service, particularly into the government assertion that the doctors and health workers were responsible for all the ills in the system. This agitation was followed by a series of agitative movements all over the country, mostly by the junior doctors but also by the state doctors in Delhi, UP, Orissa, Assam, Maharastra Andhra, Bihar - though with different demands as was expected owing to different levels of development. Everywhere, organisations of service-doctors sprang up independent of the IMA. The agitation in West Bengal also brought changes in the orientation of Bengal IMA, which despite its long history of co-operation with the government had to come out actively in support of the service-doctors and junior doctors.

Sporadic movements on various issues such as reduction of job burden, physical security at the work-site, better provisions for emergency care, improvement of rural medicare and more scope for higher education have taken place culminating in the 1983 statewide movement. The junior doctors demanded, besides bettrer pay, service conditions and provisions for emergency care and a health policy with priority to preventive care. The Left Front Government took recourse to unprecedented repressive measures using party cadres and the police. Brutal police violence on the junior doctors brought state doctors onto the scene, also in an unprecedented manner. Perhaps for the first time in the world, state doctors in their strike action withdrew from the emergency services. This was an organised retaliation of the doctors against organised terrorism of the Left Front government who reiterated the earlier declaration of the Congress regime that the doctors had no right to strike. The government had also earlier started denying the doctors the right to any agitative activity. This was strange and definitely unacceptable to doctors who had to earn democratic rights through hard struggle in 1974 when the conduct rules for the government servant had been revised. The doctors received, unprecedented public support even though they committed such so-called anti-humanitarian acts as deserting the emergency counters. The government finally had to withdraw the victimisation and punitive measures and concede the immediate demands of the strikers.

There are now indications that service doctors are now beginning to realise that the aspirations of their occupation are directly related with the nature, object, standard and extent of the state health care services. They have now raised the demand for clear declaration of the aims and objects of the state health policy and a controlling role in implementation, a plea to share responsibility with power. The service-doctors in West Bengal demanded that free state medicare be exclusively reserved for the indigent population only, which produced indignant protests not only from the privileged middle class

but a few political parties with 'Left' labels. Different mass organisations are now holding meetings and seminars on the health policy and state health acare administrtion There has also been a renewed spurt in the agitative movement of the junior doctors and service-doctors in other states for instance Bihar, UP, Orissa, Maharastra and Delhi.

These organised movements of the service-doctors brought many undiscussed issues into public attention. Should the doctors be treated as a special occupational group with limited democratic rights and additional responsibilities to society? And if so, why? What are then the limits of the forms of agitation for the doctors, if they have grievances to agitate for? Are the doctors also entitled to fixed duty hours just like others? Why should doctors alone have a moral or social obligation to serve the villagers who are deprived of, and are discriminated against in respect of all other commodities and services? Should the generalists enjoy the power and the doctors bear the responsibility of state health care service? And finally, who doctors are primarily responsible to, the employer or to the patients or to their professional ethics?

The foregoing development and issues persuade us to take a new approach — the marxist approach — to determine the role expectation and analyse the role performance of the medical profession. In a market economy, the medical profession cannot but be governed by its rules and to expect them to swim against the current is an utterly idealistic proposition. The service-doctors tend to behave as other wage-workers do. They try to extract as much wage with as little labour as possible, in contrast with the employer's tendency to extract as much labour with as little wage. It is all very well and easy to define 'medical care' as a commodity in the capitalist mode of production but it needs explaining how the universally free state medicare remains a commodity and behaves as a commodity. Or what here is the relation of production between the owners of the means of production and the sellers of labour power? It needs study to understand why the primary need of food-clothing-shelter is denied to a dying citizen but free medicare service is demanded and created and, the nature of the class struggle that brings about this state response. All these studies in the concrete reality of the Indian situation will bring us back to the question of class identification.

Conclusion

"The separate individuals form a class in so far as they have to carry on a common battle against another class; in other respects they are on hostile terms with each other as competitors. On the other hand, the class in its turn assumes an independent existence as against the individuals, so that the latter find their conditions of life predetermined, and have their position in life and hence their personal development assigned to them by their class, thus becoming subsumed under it" (Marx and Engels 1976). The individual's role in the production process, his location in the social relations of production, the productive or unproductive nature of his labour - all these form the basis of inquiry. But as regards the identification of class, the common interest, common behaviour and common action, which are often independent of individual wills, — or the common outlook towards social events, political and ideological orientations — are also important and often act as positive forces. To this Engels has drawn attention : "The economic situation is the basis, but the various elements of the superstructure-political forms of the class struggle and its results, to wit. Constitutions established by the victorious class after a successful battle etc., juridical forms, and even the reflexes of all these actual struggles in the brains of the participants, political, juristic, philosophical theories, religious views and their further development into systems of dogmas - also exercise their influence upon the course of the historical struggles and in many cases preponderate in determining their form" (Marx and Engels 1965). In order to understand the social role of a group of similarly placed wage-earners, their historical development in relation to the changes in the mode and relations of production as well as their political and ideological expressions vis-a-vis the dominant political and ideological current in the given society, are to be studied. Class is actually, a historically developed, ideologically shaped and economically determined dynamic relationship expressed through class struggle. Thompson's notion of class reveals this aspect. "By class I understand a historical phenomenon, unifying a number of disparate and seemingly unconnected events, both in the raw material of experience and in consciousness. I emphasize that it is a historical phenomenon, I do not see class as 'structure' nor even as 'category', but as something which in fact happens (and can be shown to have happened) in human relationships ... Like any other relationship, it is a fluency which evades analysis if we attempt to stop it dead at any given moment and anatomize its structure.... The relationship must always be embodied in real people and in a real context" (Thompson 1982).

The social role of the employed section of the medical profession is therefore, determined by their role in the dominant mode of production and by their interaction classes in the social events. Sellers of labour power primarily sell their labour power to earn a living not to produce commodities. By the complexity of social division of labour, some have greater interest in their products while others have greater interest in the production process. Each of the occupations has an ideologically determined skill, status and price. All have common despair in unemployment and all undergo the similar feeling of inferiority, helplessness, subordination and subjugation in relation to their employers. Vic Allen, thus describing the wage-earners, concludes that bourgeois sociological stratification of different hierarchical classes and the reductionist categorisation of productive and unproductive labourer without empirical substantation, will not be helpful in an attempt to differentiate between wage earners (Allen 1978). In the case of health professionals, the study should go much deeper and wider. Health and medicine are not mere sterile figures or say, mortality and morbidity statistics. Illness involves pain, fear and desperation in real life and these saturate the milleu wherein medical care operates. Cultural instincts and ideological creeds strongly influence and occasionally determine medicine and medicare. Medicine in its practice and institutional forms is not merely commercial exploitation or oppressive power relations imposed by the dominant class — as radicalism may have us believe — but is a resultant of class struggle, of antagonistic and non-antagonistic contradictions between classes; of interactions at the economic, political and ideological levels

The question of the role and behaviour of the medical profession is relevant to the building up of a Peoples Health Movement (PHM). PHM is not merely imparting health education to the individual or community. PHM does not end with the exposure of the inadequacy and exploitative nature of capitalist medicine. PHM needs to acquire expertise, to develop sound scientific basis of egalitarian health system, to search for the mechanics of building up of a socialist health culture and to strive for subordination of medical science to social needs and aspirations. It is a stupendous task and the role of the health professionals is crucial. This necessitates objective study of the profession before theorising study of the developing contradiction in the profession and the nature of the contradiction; the dialectics of the medicine; the development of the elements of socialist medicine during bourgeois dominance; the dialectics of cultural change and development. In the ensuing struggle the weapons of the bourgeois science and technology ought to be counterpoised by the weapons of peoples' science and technology. Involvement of the medical personnel will not be determined by humanist exhortation or so called deprofessionalisation but by class contradiction and class struggle. The medical profession or a section of it - be it categorised as the 'new petty bourgeois' (Poulantzas, 1975) or the 'new working class' (Mallet, 1975) will have its own determinant role to play and the PHM activists must need to analyse and understand this role in order to formulate the strategy and tactics in the emerging social events of the health sector.

UPSIDE DOWN MEDICAL RESEARCH

The Case of Anaemia

rajkumari narang

What conditions and influences the development of medical research ? What motivates a researcher to choose a particular problem area ? Under colonial rule research was a monopoly of a small group of scientists, mostly British some Indian. Curiosity and the need for experimentation and perhaps some concern for the suffering generated a number of interesting and relevant studies. After the '50s the orientation and the ethos of medical research have changed — the problem areas are not those which benefit the majority but those which are most likely to bring recognition to the researcher. Even when occasionally, an area of relevance such as anaemia is chosen, it is looked upon as a purely medical problem, deemphasising the social and epidemiological aspects. This results in a medical/technological solution which can at best, provide temporary relief. The author critically reviews the studies on anaemia over the years to illustrate her contention that the choice and treatment of problems in medical research is rarely governed by factors such as people's needs

Doctors and scientists from the very early part of this century belonged to a privileged class trained and employed by the British and lacking in involvement with the needs of the native population. We find however that there is a certain amount of eagerness to learn, experiment, and change things inspite of the primitive technology and little basic knowledge in the field of physiology. Although the knowledge of science was incidental and the doctors were guided by the prevailing assumptions and biases of their class, the mood of liberalism sweeping the country encouraged them to be open in their pursuits.

The science of medicine was still young and technology not so well developed. The lack of sophisticated laboratories and equipment was compensated. it appears, by more sincere attempts to learn about the lives of the poor and to look at the wretchedness of their condition that resulted in killer diseases. Curiosity and the need to experiment were also important considerations of that time. Scientists were new to the discipline and had not yet mastered it, to start the manipulations so obvious in the seventies. and eighties. This could have been the result of moral concern or a more humanistic approach.

The independence movement, world war and the general political atmosphere could have diverted the efforts of the scientists to what were seen as the needs of the country, but there was a persistence and demermination to eradicate anaemia. The callousness of the later research is absent, though anaemia must have been uninteresting and unexciting to the whites (as a condition rarely encountered in the West) and the Indians bred in their tradition. In contrast after Independence when anaemia still tops the list of killers during childbirth, scientists are bored with the problem unless it lends itself to molecular manipulation and sophisticated technology use. There is no patience or concern with the lives of the poor, or with the neglect of women, and the environment of infection and infestation. The age of cold hard objective reasoning demanded ruthlessness with the poor. The human angle was side tracked and with that out went methodical epidemeological research. If anaemia has not disappeared with the iron pills — the country cannot stop its march to the 21st century with the electron microscope, ELISA, molecular biology, monoclonal antibodies and so on. "Socio-economic problems are not the concern of the scientists", as one award winning consultant scientist to international agencies remarked. Even technology has not been used for the poor. We have sensitive tests developed to detect diabetes (less than 5 percent have it) inborn errors of metabolism (prevalent in 1 in ten thousand or 1 lakh population), but the method of anaemia detection is the same as that we had in the thirties !

Research today has stepped out of the homes of the poor, by passing the dirty lanes, open drains, concrete monstrosities and smoke emitting factories, straight into the air-conditioned labs and test tubes. Problems that are rooted in an exploitative socio-economic system are sought to be solved from the rarefied atmosphere of the laboratories. Solutions to hunger and anaemia are sought through statistical manipulations of mean and standard deviation. It seems as if scientists are now fighting by proxy the battles of the ruling classes regarding food needs, minimum wages and hunger; their scientific vision can accept strips of data fed into the com-

puter, but not the living, half dead tired women who flock to the hospitals everyday. This myopia seems characteristic of our research today. This mechanical transfer of data reflecting the lives of the poor had occurred in the west almost 25 years ago. India seems to be one of the few developing countries trying to catch up in this field. The price we pay for the use of these advanced techniques is that we loose sight of the human being at the other end. Increasingly we isolate ourselves and our research from the human reality out there. The study of the historical research on anaemia serves as a paradigm.

Anaemia : A Case in Point

In 1915 Dr. A.L. Mudaliar in the Annual Clinical Report of the Raja Sir Ramaswamy Iyengar lying-in Hospital vividly described the clinical picture which cannot be improved any further. "The anaemia of pregnancy is a malignant type of anaemia that seems to be much more frequent than is supposed — it is not only a fairly common complication during pregnancy but is one of the most fatal complications. In 1914 the disease was responsible for 35 percent of the mortality — more frequent in multipara than in primipara, and has a very insidious onset; patients hardly realised the gravity of this condition till the whole body is swollen up and they get an attack of dyspnoea when they seek admission. Breathlessness on slight exertion and extreme weakness are prominent symptoms. An analysis of the blood shows reduction in the RBC - - - - ' (Mudaliar, 1915). In 1927 Margaret Balfour from the Haffkine Institute, Bombay published her findings on Anaemia (Balfour, 1927). This is an important study by a white woman. Her meticulous observations betray her colonial background, but her concern for the enormity of the problem is real. As a woman she is also concerned about the maternal mortality due to anaemia much more than the other researchers of that time. The study is well documented with her starting observations, "In view of the frequency with which the disease occurs in India, it is surprising how little attention it has attracted", a fact which is true to this day. She adds, "This is no doubt partly owing to the fact that little obstetric practice is in the hands of medical practitioners". (Balfour, 1927). It was a period when the medical profession seriously believed that only they could understand problems and change the whole face of society. They feel that the key to the health of the community lay in their hands. Even Balfour identifies her hurdles typically "It is notoriously difficult to get a correct history from hospital patients in India" is her starting shot. The formal training of the doctor was obviously not different then. The framework in which they functioned had nothing to do with the real lives of the people. Any patient who deviated from the textbook pattern of disease was non-compliant or difficult. The woman's real experience of pain and illhealth did not fit into the classical patterns of disease. Doctors expected direct, well-defined, specific answers to their curt questions whereas the woman's understanding of pain was different. This socio-cultural void has only increased with time because today doctors donot even demand answers to questions any longer. They already know it all and have no time to ask the questions.

Nevertheless Balfour's research is exhaustive because she finds that anaemia is not just anaemia but is associated with a host of other problems such as fever 83 3 percent, diarrhoea 38 percent, Albuminurea 30 percent liver enlargement 8 percent, spleen enlargement 18 percent, oedema 100 percent, vomiting 40 percent, sore tongue 31 percent, Epistaxis 7 cases and weakness — always (It is heartening to note that an important symptom now dismissed as "subjective" and "imaginary", was actually elicited and documented). Her startling findings of 42 percent maternal mortality and 53 percent stillbirths led to the recognition of the fact that Anaemia had to be tackled somehow.

Her treatment consisted of rest, diet, iron, blood injections (i.m).,. She also visited the homes of the poor anaemics and attempted to link up the problem with the lives of the women (a rare quality compared with the clinical detachment of the present day doctors). Since the incidence of anaemia was higher among the Muslims in her study she states "—-- The main cause of this is probably the purdah condition under which Mohammedian women live. The poorer classes are confined in a single room where they lead a very inactive life. Hindu women, though under the same general conditions as regards poverty, overcrowding and epidemics, do not observe purdah in Bombay and so have a freer life '. She continues, contradicting herself "-- The Hindu woman does not go out much because customs and habits did not encourage it. - - The work of the home does not require a great deal of activity, especially if it is shared by several women. Modern conveniences also tend to reduce domestic duties (sounds familiar) while modern principles regarding physical exercises and games for women have not yet taken root in India except in a few cases. A generation ago the women of the family ground

the corn daily and fetched water from the well. Now in Bombay atleast they buy the corn ready ground in the bazar and the pipes bring the water to the poor".

These observations betray the prevailing assumptions about women. Instead of recognising that these were much needed conveniences and looking for causes elsewhere she feels that the women had no right to look sick, flabby and unhealthy with anaemia and confuses inactiveness which is a symptom of severe anaemia with the cause.

The major flaw in the study was, however, the fact that only women with haemoglobin (Hb) levels less than 50 percent were considered anaemic. Now the normal Hb level in the West was 14 gms. whereas the normal detected in the Indian poor was between 9.5 to 10 gms. Hence 50 percent (4.5 – 5gms.) of the normal in India was obviously a very precariously low cut-off point. (The cut-off point for anaemia in pregnancy today is Hb less than 11 gms). Obviously the actual incidence of anaemia in Balfour's study was much higher. She had no problems accepting lower standards for Indians. This is true of the other researchers too. They may not have had the expertise then, but they did have the information of higher standards being applied in Britain. They did not find it necessary to question the norms, nor did this upset them. *It is not surprising that science rejected and gave credence to the Britisher's view of the quality of the Natives life. In fact scientists strengthened these myths. To this day Science has fought shy on the challenges of racism, facism, sexism, or social inequalities. It has conveniently toed the line of the dominant ideology and under the garb of scientific truth has disallowed debates and questions.* In fact scientists employed by the government are true, lawful servants ! In spite of Balfour's incidence of 10 to 20 percent (the prevailing figures are 60-70 percent) the high maternal mortality rate led her to postulate a toxic condition associated with pregnancy. She could not demonstrate cure with medicinal iron etc., because we know that treatment for anaemia is very long drawn out.

In the same year McSwiney recorded 43 cases of anaemia (McSwiney, 1927). Unfortunately the hospital stay of the women and treatment was for a few days only, because women came only when they were critical and did not stay long enough to get treated after delivery. She was convinced that follow-up of the patients was not possible as "They were all poor and ignorant folk who became restless after some weeks of improvement and bitterly resented the innumerable injections and demanded their discharge at the earliest moment". McSwiney like today's doctors was unaware that women's labour was needed to run the home and care for the children and that she could not allow herself the luxury of treatment in the hospital ! McSwiney however talks of preventive treatment early in pregnancy to be followed up to term to see whether anaemia could be prevented.

The search for a "cause" of anaemia continued and in the meanwhile experiments on animals were carried out with two diets "a Hindu Diet" and a "Muslim Diet" (Wills and Mehta 1930). But it was too early to ' detect" iron deficiency anaemia by manipulating diets because contributing factors were many including Malaria, Kalazar, Syphilis, and host of other infections

In 1932 A.L. Mudaliar and K. Narsimha Rao from the Government Hospital for women and Children, Madras reported their detailed study of anaemia (Mudaliar and Rao, 1932). Their criteira for Anaemia continued to be (4.5-5.0 gms). But they had made attempts to focus on the multiple factors such as gastric acidity diet infections and others, and postulated the following theories to explain the cause of this killer disease: 1) Infective theory 2) Vitamin deficiency 3) Toxemia 4) Deficiency of Anti-anaemia factor.

A Landmark in Anaemia Studies : 1940s

Upto this point the studies were not organised, but by 1942 L.E. Napier and Neal Edwards published their report financed by the Indian Research Fund Association (IRFA) which was a major document - and has, I think, come nearest to defining the problem (Napier and Edwards, 1942). It dealt with most of the questions including Haematological techniques and included a guide for research and extension work. It is a landmark in the field of anaemia.

Part I deals with a short history of anaemia research in India and it was documented that Dr. V.R. Khanolkar was investigating into the Hb standards in health and disease. The findings of the earlier Anaemia Sub-Committee appointed by the Scientific Advisory Board of IRFA, in 1939 by MI Neal Edwards, V R. Khanolkar and S S. Sokhey was also reviewed, where the major conclusions were that the cause of anaemia is ' common to a large percentage of the population though the dominant cause will be different" and recommended a study of "normal Hb"

and incidence of Anaemia including the effect of treatment. They had also recommended the study of clinical data and diet intakes in pregnant and non-pregnant women during and after pregnancy (Napier and Edwards 1942).

The report also accepted that "In the past anaemia has attracted less attention than it deserved, partly on account of the general attitude of complacency that is adopted towards a disease state not commonly associated with a high mortality and partly on account of a physiological misconception, namely that the normal Hb in the blood of persons living in tropical countries is lower than that of the residents of the temperate climate. The misconception regarding the Hb level in the tropics has now been fully exposed — Anaemia is a very important factor in causing death in infections and other diseases in which, had the patient started with full complements of blood — they would have recovered ..." (Napier and Edwards 1942). At last there was some light at the end of the tunnel.

The report also reviews the work done on pregnancy anaemia. Significant reviews are those of Margarget Balfour where she reported that anaemia was responsible for 61.9 percent of all maternal deaths in Bombay and 35.6 percent in India (Balfour, 1927). Neal Edwards, with data from the Women Hospital gave an incidence of anaemia 49.5 per thousand pregnant women in 1936 (taking Hb less than 50 percent) and Napier and Dasgupta's figures of 158/1000 pregnant coolie women in Assam (Napier and Dasgupta, 1937).

The earlier studies had found that the causes of maternal mortality was in the following order : (1) Sepsis, (2) Anaemia and (3) Eclampsia, and report that among the cases of sepsis which heads the list, there are many cases in which if the patients had not been severely anaemic as well, they would have recovered. (It was also known that in Britain and Wales, anaemia was the cause of only 0.05 percent maternal deaths).

The review of the epidemeological data shows that the associated problems such as fevers, syphilis and other infections were very important and reported that "the discrepencies in the findings of the different observers may well be explained on the grounds that there are multiple causes and that these are not equally represnted in the various series of different observers".

Reviewing the haemoglobin level from various parts of India they seem to miss the important finding related to the socio-economic gradient reflected in the following figures :

	Indian	West
Men	14.5 — 16.0	14.5 — 16.0
Men (Coolies)	12.63	
Women (Students)	13.73	
Women (Middle Class)	12.63	
Women (Coolies)	10.5	
Women (Coolies) (Pregnant)	9.22	

Hb levels in gms/100 ml.

According to the table the poor and specially women were at a disadvantage at the start of pregnancy. This "normal" low Hb levels resulted in anaemia at the onset of pregnancy when the needs are more, and by the end of pregnancy, the condition was so critical (Hb less than 5 gms) that their symptoms were of heart failure.

They were also surprised that the coolie population of both Assam and Shivrajpur in Maharashtra had the same Hb. levels, but less than the Western levels. They at last postulated economic and dietary factors, because in 1936 Napier and Dasgupta had given iron to coolies and raised their Hb to 12 gms and had suggested that there was another limiting factor too (obviously food) (Napier and Dasgupta, 1936). In another experiment by the same authors they found that coolies who were well fed for four weeks before iron therapy showed better responses than those who were not given food (Napier and Dasgupta, 1937 b). The haemoglobin of the well fed group had come up to the levels of healthy men.

Another finding by Napier and Dasgupta was that when the obviously anaemic women had been excluded, the mean Hb was much the same as amongst non-pregnant normal women (Napier and Dasgupta, 1937 a).

Given the limitations of 1942 the scientists were very close to the truth by virtue of their keenness and determination to get to the truth. They were not looking for easy solutions yet. The major findings can be summed up :

(1) that the food intake was low in anaemics; (2) there was a massive hookworm infection; (3) there was inadequate iron intake; (4) Associated infections and other infestations. (Mitra, 1939). They had no knowledge of the following yet because science had yet to unveil some of the mysteries of the cell.

(1) The mechanics of the cell cycle, and haemoglobin synthesis; (2) Need for folic acid and other nutrients; (3) Results of experiments with radio active substances. Inspite of the limitations of that time they humbly accepted the fact that "the essential difference between the study and the treatment of a case in a sanitary advanced country on the one hand and a sanitary backward country such as India on the other is that in the latter one has always to make one's study against a background of widespread infections such as malaria and hookworms, and of malnutrition both general and special Each infection and each food deficiency must be considered as possible contributory factors ... ".

Part III of the report is optimistic because the authors are convinced that anaemia can be prevented and perhaps special anaemia clinics would help understand the "social, environmental and dietary factors ... ". It would also help treatment and research. They felt that the "hit and miss procedures" were wasteful and expensive, and the severe cases were being admitted to purdah hospitals where the facilities were absent and the pathologist who saw the slide never saw the patient. Hence "the background, environmental and personal diet and family customs must be given the same consideration as is applied to the blood slide and clinical findings".

There is a chapter on the details for conducting an anaemia enquiry and research. It is very well thought out with the women as the centre, and not the scientists ego, pet hypothesis or personal ambitions. They suggest that "questions should be intelligently considered and not mechanically noted. For example in a meat eating family the mother who may be the subject of investigations may herself take practically no meat if she eats what remains after the other members of the family have eaten. Similarly lack of sunlight entering a particular room where the woman spends 24 hours a day may be in fact of more importance than the degree of ventilation of the room".

The approach is sympathetic and explores qualitative details beyond the narrow confines of "science" as will be obvious in the more recent work on anaemia. There is another interesting human observation differentiating the moderate anaemia from severe. The authors are surprised and find it worthwhile to document that in "Moderate anaemia" the patient usually makes no complaints and is found on routine enquiry. On enquiry she may admit to feeling tired, but many women expect this in pregnancy and think nothing of it. (Today we have lost even this sensitivity that the medical profession had in 1942 ! It is seen as a subjective symptom and therefore not to be relied on). In severe anaemia there may or may not be presenting symptoms. The degree of anaemia which may develop without symptoms is a testimony to the low standard of well-being with which many women seem satisfied. Questioning will reveal increasing lassitude, shortness of breath, palpitation and swelling of the feet and face ... ".

The recommendations and the propaganda leaflets are again documents with well thought out solutions to tackle the teaching of anaemia and even "A method of haemoglobin estimation should be taught to every midwife ... " has been suggested. They cry out for early detection, and regular examination of the pregnant women.

The propaganda leaflets could be used even today because they deal with the questions of a good diet, special foods, medicinal iron, care and so on and also notes the responsibility of men " ... It is in the hands of the fathers and husbands to take steps to prevent the mother's suffering and ensure their health and safety during pregnancy and childbirth".

This optimism was understandable, because science had opened up new frontiers and the combination of scientific knowledge with the resolve to apply it for the good of womankind made everything seem possible. *The whole attempt appears like a dream today and anaemia still tops the list of killers during child birth followed by sepsis and eclampsia.*

Abortive Search for Quick Cures

Independence saw the report of Dr. S. Pandit published in 1948 entitled *Causes of maternal mortality* (Pandit 1948) — positive report still in the same optimistic mood. But major research bodies like ICMR were not touched by the strong winds of change sweeping the country. There was no sense of urgency, only clinical detachment for the next 10-15 years. Normal levels of Hb were worked out and the role of folic acid and iron confirmed. Instead of getting on with eradication, scientists

betrayed their contempt for the poor people with studies like *Role of rice diet contributing to increased fertility* (Annual Report NRL, 1956). They had jumped on to the band wagon of population control even before they were invited. From this time onwards one finds them bending over backwards to please the powers that be and "science was placed at the service of the ruling classes" even when the rest of the country and the bourgeoisie was talking of plans, people, democracy rights etc. The scientists were not impressed. They had internalised the ruling class contempt for people's lives and food needs and a lot of time was spent looking into Ducks egg protein and its virtues and the role of mothers milk in causing malnutrition. The studies on anaemia were secondary. An important finding in 1956-57 was allowed to pass by because it was not exciting or sophisticated enough (Annual Report, NRL, 1957). It was down to earth and pedestrian. The study showed that iron cooking vessels helped in increasing the iron content of foods cooked in them. Such a study obviously would not lead to international and national recognition and awards, and one could not "claim" anything for this - hence the disinterest. By now research had turned into an industry which could churn out huge spin offs for scientists in terms of patients, trips abroad, publications and awards! The new breed of scientists were not going to settle for simple iron cooking vessels.

A search for a miracle and a quick cure was launched to put an end to the nagging problem and to claim credit for having wiped out anaemia. The environment, foods, infections, poverty had to be bypassed, "All that takes time" as one of them exclaims. In the sixties sketchy details of iron needs were worked out by simple additions of the need during pregnancy, lactation, menstruation and by 1969 Dr. C. Gopalan announced the findings that iron and folic acid would be distributed all over the country as a National programme (Gopalan, 1969).

He said "Till such time as we are able to bring about a significant improvement and diversifications in the dietaries of the poor sections of our population, the *practical* (emphasis mine) answer to this problem must lie in the systematic distribution of iron to our poor pregnant women through MCH centres and PHCs". (Note the significant patronising tone!) Even this is recommended in the latter half of pregnancy because "A significant proportion of the poor pregnant women can be reached only in the latter half of pregnancy". The researcher's pragmatism must be appreciated along with his candid confession! This reflects how the researcher has stopped identifying with the subjects of research and has instead objectified them. By 1970 Dr. Gopalan even announced the well worked out doses of iron to wish away the problem of anaemia from all segments of the population (Gopalan 1970). Dr. Gopalan was of course oblivious of the problems of long distance storage, distribution, lack of commitment of the staff, the felt need of the women, the massive problem due to inadequate food, overwork, infection and anaemia was reduced to a farce, by the pill. It was not the fault of the women that it did not work. Any wonder it has not even been evaluated!

In the meantime the WHO in 1968 had recommended fortification of food with iron, one of the exciting new suggestions that would increase iron in food, and do away with pills (WHO, 1968). Hence work was started at the National Institute of Nutrition to identify the chemical composition of an iron compound that would mix well with common salt (which is consumed by all). The research was time consuming because the hurdles are numerous. The drug (tonic) industry watched this progress with apprehension but they need not have feared because since iodine fortification of salt in the goitre area had been a failure - it was a foregone conclusion that this research would remain a curiosity until such time as the system became really concerned with the poor.

Upside Down Research : 1970s

In the seventies it was forgotten that anaemia was still a killer, it again became an "exciting problem" and gained fresh recognition. Anaemia means less blood, less oxygen and (?) alteration in utilisation of food for energy for work, with many other associated changes. Hence while the researchers now marked time waiting for anaemia to disappear, their curiosity was raised with questions of anaemia and immune response, anaemia and work output (we had studies on the same plantation coolies in the Nilgiris by Dr. Rahamatullah, who made anaemic women (Mean Hb. 6.2 gms.) work and calculated the increase in work after they were given iron (Rahamatullah, 1983). There were also studies of alteration in the immune response in anaemics, and other molecular level changes such as changes in enzymes functions.

In the meantime by the late seventies when anaemia could not be wished away nor used for "exciting" research we have a breed of scientists

who were willing to flog a deadhorse—the pay offs would be recognition, awards etc. It was obvious that anaemia had to be presented differently. Hence statistical jugglery was resorted to in thousands of anaemics showing that anaemia had a role in prematurity, stillbirths, abortion, IUCD, Pill use. maternal and child morbidity, toxaemia, body weights, arms circumference, skinfold thickness, sore tongue etc. Research had now been turned upside down. (Ann. Reps. NIN 1979-83) *The causes of anaemia were no longer important — the correlations with absurd parameters started, and by a process of elimination the researchers arrived at the "Risk Care Approach" a bastard of the eighties* — an attempt at planning for the 21st century by efficient and smooth salesmanship based on statistical manipulations (ICMR, 1985). It states that indices of MCH care like low birth weight and prematurity rates — have not shown the decrease commensurate with expansion of health services — an attempt to cover the entire vulnerable population (pregnant and lactating women, infants and children) with the available limited health man power — might have prevented effective functioning and resulted in lack of perceptible impact ... and "Dealing with problems of large magnitude with available limited resources, adapting a risk care approach might pay higher dividends —''

The health care system was now using the language of the stock exchange. The philosophy being that since only a small section of women are really in the "risk group" — contributing to mortality, the others may be in the border line — and never mind about them — they should be identified and treated. There is no concern for the quality of life, the nagging tiredness and the inability to work. Further it is felt that in the rural communities it is not possible for the doctor to visit far flung areas and hence one must find out the minimum number of antenatal visits needed. (Ann Rep NIN, 1982).

By process of statistical elimination the following women are placed in the "Risk Group". Hb - less than 8 gms Wt - less than 40 kg; Ht - less than 140 cm. Any other problems during the earlier pregnancies.

Other scientists impatient with the slow progress of the tablets devised ingenous methods of injecting the whole dose of iron into women (who had Hb less than 8 gm.). Exploiting the popularity of injections in our country, scientists recommend large scale injections of iron to overcome the non-compliance of the patients and cover up thus our lack of will and perseverance in tackling the problem of anaemia. (Note the similarity to the use of Net-en in F.P. Programmes).

Considering the huge government funding that goes into research today, the question that faces us is one of ethics What is the researchers' responsiblity to society? What are the attitudes and assumptions that should inform his/her research? Is s/he justified in sacrificing even scientific rigour to expediency. Should not a sense of humility underline every piece of research undertaken and attempts be made to make it relevant to the needs of the people? Today the role of science in solving the problems of the people is being increasingly questioned. If the scientists do not recognise how enormously privileged they are at the cost of the country and attempt to fulfil even the limited tasks before them they are in danger of rapidly becoming redundant.

SOCIAL DYNAMICS OF HEALTH CARE

The Community Health Workers Scheme in Shahdol District

imrana quadeer

The Community Health Workers Scheme was introduced ostensibly to promote people's participation in the delivery of health care. The scheme did not however envisage other changes in the health infrastructure or incorporate new developmental strategies. The article examines the impact of the rural social and economic realities on the scheme in Shahdol district of Madhya Pradesh where it was introduced in 1977. It shows that the prevailing network of linkages which serve only to increase and strengthen the hold of the elite, have fully absorbed and distorted the scheme. The poor who were the supposed beneficiaries, had no say in either the decision-making or the running of the scheme. The author concludes that in the absence of efforts to either change the social matrix or at least control some of the key components, schemes such as this one are bound to fail.

The Community Health Workers (CHW) Scheme was introduced to the Indian health services panorama with many promises. It was to promote people's participation, provide health care to the poor and deprived rural population, and be the vanguard of Primary Health Care in the Indian setting. A constant refrain in the planning process was the need to revive self-sufficiency in Primary Health Care and make it a part of the broad developmental process.

The scheme however, was introduced without any significant changes in the health service infrastructure which was to support it. It simply took over the responsibility of implementing the existing health programmes without any review of priorities and the technologies used. The general developmental strategies remained as stagnant as ever and above all - despite all the laudable objectives - the rural population was treated as one homogenous mass without taking into account the reality of social classes and their dynamics. The implications for the working of the scheme were quite serious. This paper examines the impact of the rural social and economic realities on the working of the scheme. It is based on a part of data collected for a study of the CHW Scheme in the pilot blocks of district Shahdol in Madhya Pradesh. The research team consisted of three research investigators.

Methodology

Our hypothesis was that the Scheme's actual performance would be determined by the nature of social dynamics in the area and the official efforts made to overcome the constraints imposed by these dynamics. The aspects that we focussed upon were : (a) Social and economic stratification of the rural population; (b) the links of CHWs with the village strata; (c) the links between strata which indirectly influenced the behaviour of its members; and (d) the links with the personnel of the health services.

These were the areas which we explored through observations, interviews and group discussions with people of different strata, the CHWs and the PHC staff.

The study population consisted of the first pilot Block selected for the implementation of the CHW scheme. This Block had a population of 39,642 with 109 villages in all.

General surveys were conducted in 34 villages from where CHWs were selected and in 4 villages which did not have CHWs. These surveys were used to understand (a) the socio-economic background of the villages, (b) to explore the views of village residents regarding the scheme and their CHWs, (c) to collect information about the CHW, and (d) to assess the status of other developmental programmes.

For the purpose of this survey, two strata were identified : the "elite" who were defined as the surplus producing farmers,[1] regular government employees, and those who held official positions of Sarpanch or Upsarpanch; and the "poor" who were the marginal or subsistence farmers and the landless labourers. From both the strata, a 60 percent purposive sample of households was interviewed singly or in groups. The total number of households in the villages covered was 3,743 and their population was 20,534. Out of this the sample covered 19[illegible] elite and 2194 poor households. The malaria worker's house list was used for the purpose of identification and 1 to 2 days were spent in each village by the three investigators.

In six selected villages where the 'best'[2] CHWs resided an intensive survey was carried out. About one-two months were spent in each village. For this in depth study three strata of households were identified based on landholdings and employment. These only roughly coincided with what we considered well-off households, subsistence farmers, marginal farmers and landless labourers but they sufficiently reflected the economic stratification of the village population.[3] The categories were of households owing 0 to 5 acres of land, more than 5 to 10 acres of land and more than 10 acres of land along with those having permanent employment in the government services (Table-1).

The intensive study provided qualitative data on socio-economic aspect of village life, health and health care services, developmental programmes, CHW's work and popularity, and his interactions with PHC personnel as well as the people. For quantification of some of these, an interview schedule was administered to a 30 per cent stratified random sample of households.

In addition to these surveys the PHC personnel were observed and interviewed in detail regarding their views and support to the scheme. This was cross-checked with the CHWs as well.

The Pilot Block and the Socio-economic Back ground of it's People

Covering an area of 5125 sq.km., this Block retained parts of the forest which covered the entire district 30 years back. It had 19 panchayats (all Reserved) and 109 villages. Except for one railway line and two metal roads which cut across the Block, its transport was mostly through mud roads. It had a coal mine, and a thermal power station was being proposed within its boundaries. The Block had a higer secondary School, 72 primary schools and 10 junior high schools. Its tribal population was 25,704 and scheduled caste population was 1830.

Size and Social Composition of Villages Surveyed

All the villages were predominantly tribal. They could be grouped into 12 villages which had a few Scheduled Caste households (group I), 15 villages with 1-2 households of the Hindu upper castes (group II) 7 which had 10 percent or more households belonging to the upper castes (group III) and 4 where the muslim population was significant (group IV).

Although these villages were commonly referred to as tribal villages, they could be called tribal only to the extent that the majority of their residents belonged to one tribe or the other. The organisation of these villages, their economic relations and their social rules had little which could be called exclusively tribal. The small minority of non-tribals in the village maintained a posture of superiority and freely referred to the adivasis (tribals) as "Stupid' and "lazy", and blamed their character for their impoverished living conditions. A slightly deeper look into the dynamics of these villages, however, brought out the real mechanics of these characterisations.

Economic Stratification

Estimation of households owning 0 to 5 acres of land (poor) and those owning more than 10 acres of land or employed (well-off) gave an idea of the economic stratification in these villages (Table 2).

The stratification, seen against the social background of the villages, brought out some interesting features of socio-economic patterns. Six out of the seven villages of group III had the largest numbers of well-off farmers. Most of these villages were also the larger villages of the Block which were well-connected and provided employment to a significant percentage of their own population. Secondly, employment in the colliery was a significant reason for the observed percentages of well-off households in all villages, especially Group I and Group II villages. Villages of Group IV alone had no such households. Most of their Muslim and tribal inhabitants worked as rickshaw-pullers or as wage-labour in the nearby town.

Another striking characteristic of the pattern was that percentage of households owning not more than five acres of land increased from Group IV to Group I. It was also evident that the non-tribals generally constituted the bulk of the well-off farmers or the employed residents of the village whereas the adivasis were the poor, landless, or marginal farmers. Though all non-adivasis were not always well-off, invariably the Brahmins, Thakurs and Jaiswals, if they did not have sufficient landholdings, had the few available government jobs and had captured whatever other employment opportunities existed in the area.

Yet another feature that emerged was the large number of poor and ill-fed people in spite of a significant number having land. Only in 19 villages the percentage of landless was 30 percent or above. Thus, having land was not necessarily a guarantee against poverty. It was not uncommon to find

households who owned land but had no means to use it. Often the land was too difficult and unproductive to labour upon. So they preferred to do wage labour rather than toil on an unpredictable piece of land.

The Web of Life

The pressures of production processes knit the people to gether into a web of social relations the terms of which were determined by the nature of production, the intensity of needs, and by the paucity of economic alternatives in and around the area. Agriculture was the major activity binding people together. The marginal and poor farmers owned 1 - 5 acres of land and were able to produce grain which sufficed for 2—6 months. Together with the landless they constituted 31-80 percent of the surveyed population. These farmers depended upon their labour to earn for the rest of the year. The subsistence farmers were those who owned land and could produce enough for the year with family labour alone. The rest we called middle farmers or the well-off farmers who employed labour and also managed to produce some surplus. They constituted 0—45 percent of the households.

The forms of labour exchange varied from fixed period contracts "Harvahi", daily payments in barter system "bani mazdoori", to free use of the plough for two days in exchange of five days of labour "Podika", and loaning of bullocks for a season in exchange of grains. The wages were either two kilos of paddy or Kodu a course grain daily or 240 kilos of paddy or Kodu for four months of Harvahi. Sometimes, instead of this, the Harvahi was given 12 kilos of grain to sow on a piece of land. The produce was his except for the land rent that was deducted. Yet another form of exchange was working free of cost for each other at the time of sowing and harvesting, a practice most common among poor and marginal farmers. Wage labour was uncommon and money as payment was offered only by farmers who were essentially colliery employees. Very often even these terms were not available to people who then depended upon collection of forest produce and fire wood.

The subsistence farmers using family labour just about managed to eke out a living. Their sole concern was to remain operational and they consequently tended to keep aloof, being always on the look-out for odd jobs to supplement their income.

The artisans were few (Basorth, Agaria, Chamar, Lohar and Kumhar castes). Their trade was dwindling in the face of competition put up by the growing industries. Many did wage labour and farming as well or had completely shifted over to these.

The non agricultural labour was yet another cog in the wheel, exploited both by the contractors and government agencies. Paid around Rupees three a day in spite of the existing minimum wages, the labourers had to seek employment with these very exploitative agencies because, firstly, the contractors and private businessmen were hand in glove with each other and secondly, there were no other alternatives.

Through these working relations, the poor found themselves entangled in an exploitative network but knew of no ways to get out of it. Even though the well-off farmers were unable to provide work to all who needed it, they wielded power through their ability to provide odd loans (of seed, grains and money) and "sifarish", (influence).

The well-off were thus left alone to make their own profits, not just through land but through most of the administrative agencies which existed in the area and which were supposed to deliver help and relief to the poor. One example of this was the Panchayats, which worked as tools to soak up public resources for private purposes. The Block Development Officer worked through them and through the village elite and so managed to reach only a small section. The elite used their sources and their contacts to exercise their own power and to consolidate the conditions of their own family members. As a matter of fact, the word 'elite' in the context of these 38 villages is a misnomer. What we really had was a handful of not-so-affluent families who, either because of their caste Hindu background and past power, or because of their land holdings, had acquired respectable positions. 'Respectable' because they were the ones who entertained, hosted, and informed visiting officials, police personnel, and, at times, politicians, and they were the chosen few for delivering to the people whatever the Block administration had to offer. The intensive study showed that only a few in category III performed this role.

It was not uncommon to find that in these villages the lowly paid but most sought out positions of CHWs, Adult education tutors, and Rahatkar relief work mates had been captured by the same persons belonging to these families or the family of the Sarpanch or different members of his

clan. It was here, then, that caste and family loyalties began to influence the economic relations. The opportunities were few and unemployment vast. With the majority of adivasis being unacquainted with laws, rules, and functioning of the administrative system, it was not difficult to usurp (with the help of higher officials) what was meant for them. Still better was the practice of including one or two of them, giving them a few crumbs, and getting their thumb impressions on the official papers. The divisions within the adivasis and the influence of Hinduism, which had brought in with it the concepts of superior and inferior tribes, helped to ward off any dissent. The Raj Gonds, who considered themselves Khsatriyas (Thakurs) through their social superiority as well as land ownership, were the closest to the bureaucracy.

The landless and poor lived in fear of the local administrative machinery. In the event of an encounter they would rather let the 'Bare log' (big people, the rich) of the village play the intermediary than face them on their own. It was a common practice to pay the Sarpanch to get one's work done rather than do it oneself. The officials, however, perferred a system of direct payment. The police and the Patwari were the two most feared officials. Every village had people complaining of land disputes where, simply because they could not pay them, either their land was transferred to others or they were threatened with 'benami'. The experience at the Tehsil office was no different, where every clerk wanted his pound of flesh. If any one tried to bypass this system he either never got his work done or he was so entangled with the "rules" and "laws" and all the loopholes that go with them that he was left utterly bewildered. It was basically to avoid this unfamiliar world of "Kanoon" (law) that the people were forced to part with their hard earned money. It was no wonder that they were mortally afraid of the "Sahibs".

The petty traders who brought off the produce of the farmer or their forest collections were another link in the chain of exploitation. Since people needed oil, salt, clothes, and other necessities they had to exchange some of their produce for money. This exchange occurred at harvest time when grain prices were lowest and the poor farmer invariably lost in this exchange. He in fact lost twice because, soon after his own stocks finished he had to go back to the same traders who now sold him his grain at double the price. Similarly, the forest produce collected by the villagers were bought at throwaway prices and the same were sold at 200 percent profit in the market.

Introduction of the CHW Scheme

It was within such conditions that the CHW Scheme was introduced in the Block from 2nd October 1977. The implementation was done in a hurry. The PHC staff had only a week to inform panchayats, do the propaganda in the villages, complete the formalities of selection and make logistic arrangements for the training programme. The staff had severe reservations about the principles of the scheme (that health care through non-professionals is possible) and the abilities of the local population. Also, they were reluctant to take any additional work responsibility so they followed the dotted lines of the state circulars and did not bother to take initiatives in preventing the selections from being distorted by the existing power balance.

Selection Procedure

The result was that the selections were left to the discretion of the panchayat and therefore, effectively, to the whims of the Sarpanch or the Upsarpanch. In the majority of the panchayats, neither were all panchayat members contacted, nor all villagers were informed. Only those applicants were encouraged whom Sarpanches favoured. Very often the PHC in fact strengthened the hands of the Sarpanch in selecting undesirable candidates due to caste, class, and religious links and justified themselves by saying, "if others are doing it why shouldn't I". For 40 positions only 54 applications were forwarded, of which from 30 villages single applications were received. In ten villages the tie was either between members of the elite (mostly non-tribals) or among the many relatives of the sarpanch. In two cases rejected candidates were finally accomodated by creating new village clusters for them. This showed that not only the supervising staff but also the doctors and the Block Development Officer participated in the manipulations. According to some of the PHC staff members, "most of the Thakur and Brahmin candidates were no good compared to some adivasi candidates. But the lower educational level of the latter were used as an excuse to reject them". They felt, "relations and connections were more important than qualities" and said "the discretionary powers of the selection board always favoured the elite".

Of the 36 CHWs interviewed, 22 said they were informed by the Sarpanch about the scheme, 12 said the PHC staff told them, and only 2 had heard

of it from their friends. Invariably, those called by the Sarpanch were asked to apply for the training. None was told to inform others.

The general survey as well as the intensive study revealed that the majority of the people had no information regarding the scheme in general or the selections in their villages. This was particularly so for category I where 88.2 percent expressed no knowledge of selections (Table 3) Among those who expressed knowledge of the selection process, none thought it was their responsibility also. People considered Sarpanch or the hospital to be responsible for selection of CHWs in 45-50 percent of the households.

Background of CHW

Sixty percent population of the block was of scheduled tribes or castes. Despite this, of the 37 CHWs selected, only 20 were from adivasi households and none from the scheduled castes. The reasons for such distortions began to unfold when we looked at the socio-economic backgrounds of these CHWs.

Social Background : The majority of the CHWs were Brahmins and Thakurs among the non-tribals. Even the lower caste Hindus had a very marginal representation (Table 4). It was revealing that the tribal CHWs came largely from those villages where the entire population was either tribal or some lower caste Hindus lived there. In those villages where 10 percent population or more was caste Hindus or muslims, invariably all CHWs were non-tribals. Even in those villages where only 1-2 caste Hindu families resided 53 percent CHWs were non-tribal.

Our data further shows that except for seven CHWs who were not related to the Panchayat members, all others either had links with past or present panchayats or were themselves Sarpanches or Upsarpanches (Table 5). These links were common to adivasi and non-adivasi CHWs and indicated close-knit elite groupings whose members kept interchanging their positions in the power capture game. Yet another link of the CHWs was with influential families of their villages (Table 5c). If we take this into account then even out of the seven CHWs we are left with only four who could claim no links with the power elite !

Land Holdings and Occupation The land-holding pattern of the CHWs was very different from that of the general population. It reflected their links with the landed sections (Table 6). It also brought out the differences between the tribal and the non-tribal elite quite clearly. Not only the tribals owned comparatively less land, their families alone depended upon wage labour. Only three out of 20 tribal families had an employed member while among the non-tribals six out of 16 had employed members.

The CHWs themselves had varied occupations in addition to their health work. Eight did farming also, four were big contractors, and four had become professional practitioners of sorts. Eight had managed to get the supervisor's jobs in relief projects while two had become tutors in the adult education scheme. Another three had managed to get both these jobs at the same time while the remaining seven did odd jobs like taking contracts for bidi leaves, shopkeeping and so on. The relevant fact is that the 17 who owned over 15 acres also held the most paying occupations like contract work, professions of sorts, and large farms ! Also it was significant that, despite a scarcity of jobs, this small group had managed to acquire multiple employment.

Education and Age Twenty percent and 30 percent of the adivasi CHWs were high school and middle pass respectively as against 41 percent and 47 percent of nonadivasis with similar achievements. The low achievements of adivasis only underlined the irrelevance of making middle school a criteria for selection.

The desirable age of a CHW was to be over 25 years of age. In this Block however, twenty three (64 percent) were under 25 years of age.

Performance The general survey data helped to group CHWs into four groups based on people's responses. Of the 34 villages, in 15 the elite as well as the poor talked well of their CHWs, in 4 the elite talked well but the poor wer divided, in another 12 the poor as a whole were dissatisfied, and in three both categories of households were dissatisfied.

The elite, despite their satisfaction, said that the CHWs were useful only for minor illness. They were neither aware of the scope of principles of the scheme nor of the duties of CHWs. He was considered a paid PHC employee. The non-tribal elite were often patronising towards their tribal CHWs. For example, they commented, "He is the only educated one among them and education has put some sense in him"; "The poor fellow can treat only according

to his intelligence, how can he go beyond"; or, "The boy is sincere, he always comes to ask if any thing is required". For the non-tribal CHWs however, the tone changed to "He is very intelligent and we hope that he would be considered for more than just a Swasth Rakshak". "He does so much more than the health worker and is still so poorly paid"; or "The non-tribals have done well in all spheres and CHW is no exception". The well-off tribals, on the other hand, were protective about their own tribal CHWs and even tried to cover up their faults, but if they had a non-tribal CHW, they were cautious and respectful and talked in appreciative but subservient tones of the 'Bhaiyyaji' or 'Babu' (big brother).

In villages where the poor were divided in their opinions the population was generally mixed. Here the social group to which the CHW belonged invariably favoured him, like in villages Medki, Dhawrai and Khickkiri. In Badwahi the Brahmin CHW was unpopular among all the tribal poor except for the Baigas who expressed satisfaction Baigas also happened to be a landless majority who worked for the Brahmins and were almost bonded to them as labourers.

According to the poor the CHWs charged for giving them drugs and often even for chlorinating wells They said that instead of visting the houses of the poor the CHWs preferred to go to the nearby villages where they could practise easily. The Harijans complained that their houses were never visited, "He is for the 'bare log' and not us", "We dare not ask for help, if he gives something it is our good fortune but there is none with such a fortune". Despite their views this section of the villagers was keen not to get into trouble for talking, "We don't want any more trouble".

In villages where the CHW did not reside, people were familiar with his curative functions but had not seen their CHW for months together. When people's views of their CHWs are seen against the data on the CHWs' socio-economic backgrounds, some of the trends that emerge are revealing. All CHWs who were given satisfactory rating by the poor as well as the rich were tribals except for 1 out of 15 in this group. On the other hand, those who were not liked by the poor but liked by the elite were non-tribals mostly, 9 out of 12 CHWs in the group. The distribution of tribal : non tribal in the other two groups was 2:2 and 1:2. Given the distribution of villages, it naturally follows that the popularity of CHWs among the elite as well as the poor was higher in purely tribal villages (58.3 percent) where CHWs were also mostly tribals, whereas their unpopularity among the poor alone was higher among the mixed villages — 8 out of 12, i.e. 84 percent villages, where most CHWs were non-tribals.

In addition to the findings of the general survey the intensive study of six villages brought out the following significant findings.

Nature of Services Provided by the best CHWs

These CHWs were considered helpful by the people. However, their performance over the year had declined remarkably. Thus in the villages where they did not live they had stopped paying their usual visits or they went only once or twice a month. In the residential villages also, people felt that the CHWs initial enthusiasm had died down. Even then they agreed that the CHWs did help in illness. Their utility in minor illness was acknowledged but there was a significant difference in the response of the three categories.

Allopathic treatment was used alone or in combination with other forms of treatment by 55.0 percent, 76.8 percent and 92.2 percent of the households in category I, II, and III respectively. The reasons for this difference were more economic rather than a matter of preference. An important fact was that the CHWs were the source of allopathic treatment (alone or with other sources) in 39.0 percent households of category I and 26 percent in category II and III. Apart from this higher dependence of the poor on CHWs, it was also important that the poor combined CHWs with traditional healers and the well-off with hospitals ! (Table 7.)

For major illness the use of allopathy was markedly higher in all categories (80 percent or more) but the use of CHWs was much less. Even then, out of all households using allopathy, the highest use of CHWs was by category I (40 percent), the lowest by category III (14.8 percent). This was an interesting finding which indicated that the poor now had health care facilities which they did not have before. The information on the CHWs' preventive activities, their free accessibility and their practice patterns however, reveals the nature of this success.

CHW's preventive activities in the area of chlorination of wells, maternal and child health, education and environmental sanitation were almost negligible. Only 31.7 percent category I households (as against 0.9-2 percent of the first two

categories) said CHWs chlorinated wells in their houses and even they were not aware of their other activities (Table 8).

In the beginning the CHWs used to visit different areas of their residential village and the villages alloted to them but this had now become a rarity. People now had to request them to see a patient. Though these CHWs helped according to most people, 29 percent households in category I said that the CHWs refused to come and see a patient. Also, 28 percent of the poor said that he charged for injections - indulged in private practice - as against 16.7 percent and 3.9 percent in category II and III (Table - 8). In addition, in case of major illness, even category I households paid in 84 percent of illness although they used CHWs to the maximum 40 percent This indicated that though the CHWs were mainly used by category I, the trend showed replacement of the "traditional Gunia" a by a "modern Gunia" rather than emergence of self help and self-sufficiency.

Supervision : The scheme envisaged supervision by the community in administrative matters and the PHC in technical matters. However, high percentages of households in the first two categories said they knew nothing about supervision (Table - 3). Even those who mentioned panchayats separated themselves from the responsibility since there was no identification with the panchayat at all. The Sarpanches themselves were least inclined to be active in this aspect. In fact since they were a party to the selections and mostly related to CHWs, even in cases where people were unhappy they found no reason to act against the CHW's interests. Of the 19 panchayats, none had taken any action against any CHW at any point of time nor made efforts to stream-line the CHW's activities.

Five CHWs were themselves Sarpanches and Upsarpanches and they said that their panchayats had no directives about the panchayat's supervisory responsibilities. Even among the CHWs, only 3.5 percent had heard of the panchayat's supervisory role.

The technical supervision by the PHC staff was more a bone of contention rather than an asset. The Health Workers attempted to pass on their work to CHWs, boss over them and treat them as subordinates. The CHWs resented this once they realised that the PHC workers were more interested in private practice. Some were also able to retaliate given their social status and acquaintance in the village. The extent to which this conflict developed was largely determined by the socio-economic backgrounds of the CHWs The non-tribal CHWs were assertive, dominating and socially powerful. They either cared little for the paramedical workers or were treated well by them out of sheer desperation. Among the tribals, the resourceful CHWs (Sarpanches or well off) managed better since their local status was important but the others fared poorly. They were not only not given any help by the various PHC workers but also treated with much contempt.

The role of the senior staff at the PHC and district levels was not much different. All the doctors and most of administrative staff came from non-tribal caste Hindu backgrounds and had their own views of the social reality. In their busy schedules of working for Family Planning programme, Rahatkars, office administration, and looking after the 'VIP' visitors, the District Health Officers' only contact with the people of the area was through their private practice. For them the 'locals' were a mass of backward and unintelligent humanity with whom it was difficult to communicate. Condescendingly, the DHOs let the PHC medical officers handle the scheme. They themselves were hardly familiar with it. According to the two consecutive DHOs, 'What can these untrained locals do; let them atleast help our health workers". For them even the village Mukaddams and the Sarpanches were "unintelligent people". Given the choice, they were for closing the scheme any day.

At the PHC, except for one medical officer (out of four) all the rest were either indifferent or vocally against the scheme even though they agreed that the CHWs were giving some help to people where their own workers had failed. Interestingly enough, all these medical officers used the CHWs influence to get referred cases for their private practice. This link was strong and in return some CHWs were patronised by the medical officers. Their usual answer for letting things pass was, "we have no control over the CHWs and the Panchayat doesn't act. Even if we report something there is too much political interference and we know that except for getting unpopular we won't gain much".

Discussion

Our data projects a pattern of social reality wherein a handful of the non-tribal elite in collaboration with the well off tribals controlled the majority of the poor — individually through terms of work and collectively through social institutions like

panchayats. Both tribal and non-tribal poor had little access to the Block's developmental agencies. The areas general backwardness precluded alternatives to the existing pattern of living. Further, there was a general lack of information and education and the interaction of the majority of the poor with the outside world was extremely restricted. This meant that their dependence on the elite and the dole provided by the state was total. As a result, the two in collaboration got away with many acts of ommission about which the people may know but could do nothing.

In such a setting, the exercise of giving "people's health in people's hand" through their 'elected representatives' may sound good on paper but is bound to get mutated by the social matrix within which it is placed. This is what happened to the CHW Scheme in Shahdol. Though officially it was a voluntary scheme, a scheme of the people, it continued to run — despite reminders from the state — as yet another of the government's unsuccessful schemes.

The relevant aspect of the problem is that though the scheme did not work according to plans, the CHWs did cater to certain needs of the village population. It is thus apparent that while the explicit design of the CHW Scheme had not worked, there was an implicit design to its functioning. This design can only be recognised when we look at the linkages of the CHWs with the other categories, as suggested by the hypothesis of our study.

Links between social classes

The influences of the existing socio-economic configurations on the working of the scheme are clearly visible through our data. The supremacy of a small group of landed elite who controlled the local resources and also the channeling of government funds, created a situation wherein the appropriation of resource and labour had become a part of life. The CHW Scheme provided employment and therefore could not escape the general trend. Appropriation of opportunities provided by it not only brought economic assets for the local elites and their families but also an opportunity to strengthen their social positions by favouring some who mattered. The undemocratic functioning of the panchayats only made the task easier. Following the initial grabbing of positions however, the enthusiasm reflected by the panchayats dwindled into apathy and disinterest when it came to supervision and control. In other words, after providing patronage to their favourites the panchayats resumed their usual slumber.

It is also important to realise that the Panchayats could get away with this usurpation of the scheme only because people were in no position to protest against those who controlled the implementing institutions, given their social and economic as well as political dependence.

Given the domination of a small section of the population, there was no social pressure on the selected CHWs. Those who did work had their own motives. They were either interested in building their social images or were politically motivated (as the CHWs of Gijri and Varamtola) or had monetary interests. They some times augmented their 'salaries' (honorarium) through indulging in private practice and nobody objected to it. Even those CHWs who were considered good by all showed preferential treatment towards category III households. They charged them less frequently, were readily available to them, and also provided some preventive services however meagre those may be. But the CHWs relationship with the well-off was contradictory. While they served them well, they were used less frequently by this section and only for minor illness. In return for their services though, the well-off protected and praised them and thus ensured the high cost of medical services for the poor.

The CHW in general knew that if they could humour the well-off they would be free to handle the rest the way they wanted. This trend of ignoring the poor was so dominant that even those few CHWs who came from the poorer families often tended to ignore their own kind and over a year, had learnt to reproduce the behaviour patterns of their better-placed colleagues. Thus, they were either practising in their own villages or going to areas where no CHWs were posted and the people knew nothing about the scheme so that they could sell the medicines with ease.

Despite their ambiguous beliefs the majority of the poor opted for allopathic treatment if they could afford it and had also realised the importance of chlorination of wells and vaccinations. In procurring these services however, the people had learnt that money, connections and 'sifarish' were the tools that worked. Voluntarism on the part of the provider and organised demand on the part of the recipients had not been a part of their experiential base as was clear from their experience

of the political processes which moulded the administration of the area.

Links of CHWs with Social Class

Yet another crucial link was between the CHWs and the existing social classes. This was responsible for the quality of selections as well as work of the CHWs. As we have seen, only 4 out of the 36 CHWs could be said to represent the average villager. The rest had their connections with the present or previous office bearers in the Panchayat or came from the better-off families possessing large acreages of land or other business. Since this section of the village population appropriated all resources coming for rural development the CHW scheme was also appropriated. This explains the atypical background of the majority of CHWs as also their ability to acquire other employment. Consequently, not only were there a large number of non-tribal CHWs but the quality of their work in general was affected in several ways.

Firstly, since the CHWs were given the protection of the elite they could do almost what they wished without being answerable or accountable to anybody. In turn the panchayats, the statutory body responsible for their supervision, took no action against them.

Secondly, since the CHWs joined the scheme as a means to augment their income or status they concentrated almost entirely on curative work. Whatever little preventive measures they implemented in the beginning was also given up over time or else they would even charge for chlorinating wells.

Thirdly, since income generation was possible only through charging for their services and furthermore, since they could not very well charge those elite families through whose benevolence they had become CHWs, the brunt of paying for their practice was borne by the poor. Additionally, it should be remembered that the poor had no one else to go to while the well-off preferred to go to alternative health facilities like doctors and hospitals — particularly so in case of major illness. This explains the paradoxical situation of the poor using the CHW more and paying more too.

Fourthly, most of the CHWs were appointed through the agency of the Sarpanch or Upsarpanch but once they themselves became familiar with the bureaucracy and the government officials they began to develop their own alternative income sources. Thus, the post of Sarpanch would become far more lucrative as would the positions of Rahatkar mate or petty contractor. As a consequence, these alternatively more profitable occupations would demand more of their time and energy and the quality of work in community health would decline. Even the house visits being done initially would stop.

Fifthly, even those few tribal CHWs who came from poorer families were drawn into the search for better incomes and thus began to ignore their own social strata. It would be unrealistic in such a context to expect them to remain devoted to the cause of the poor.

Links with the Health Bureaucracy

The notion of their own social and technical supremacy generated a feeling of contempt for the CHWs among health workers at various levels of the health services hierarchy. The result was indifference, condescending tolerance, and disinterest among the senior officials, and jealousies and resetment between paramedical workers and CHWs who had captured the clients of the field workers and had now replaced them as doctors!

The health and welfare bureaucracy did nothing to reverse these trends. Given their own needs and links with the local elite they only used these patterns for making profits. They in fact, often protected the defaulting CHWs and never made efforts to streamline their work by either putting pressure on the panchayats or their own organisation. In the process they only reinforced the existing patterns rather than improve them.

Conclusions

Given the indifference, inefficiency and ineffectiveness of the health bureaucracy, the powerful hold of the elite, and the collaboration of the well-off tribals as well as the administrative bureaucracy of the district, the prevailing network of linkages had fully absorbed and distorted the CHW Scheme. The poor, in whose name the scheme was launched, were made to pay heavily for receiving some medical care while they had neither a say in decision-making nor a hand in the running of the scheme. It is a paradox that the well-off, who used the CHWs the least, were also the ones who were bestowed with the CHWs' attention and the poor, who used them the most, had to beg, plead, and wait. This 'success' that the scheme boasts of is certainly not an achievement but a reflection of the dire need of the toiling people.

Our study concludes that people's participation in a health care scheme cannot be an isolated event. The degree of participation (or non-participation) is determined by the overall socio-economic relationships which bind a population and within which all schemes have to function. It is these links with the larger system that decide the success or failure of a scheme. Though confined to a Block, our study identifies the social linkages which influence the scheme and underlines the fact that it is the nature of these linkages which is crucial for the scheme wherever it is introduced.

The experience of Shahdol teaches us that in the absence of efforts to either change the social matrix, or at least control the key components influencing the scheme, or offering people a taste of free preventive and curative health care services, to expect that people will hail the CHW Scheme as their own and that they will also have the strength to control a truant CHW, is far from being realistic. This, in fact, amounts to protecting the holy cow of people's "participation", irrespective of its social context.

Notes

1. Those farmers who could sell their produce for profit or could save it for the coming year.
   (These villages were mostly so poor that indentification of such households was never a problem and every one knew which households could save or sell after consuming two meals.)
2. Judged on the basis of opinions of villagers, PHC doctors and paramedicals.
3. This stratification was used firstly, because it sufficed for the purpose of the larger study, and secondly because the information required was easily available. For a more rigorous class analysis however, land holding alone is not sufficient.

Table – 1

Categorisation using Land Holding and Employment Status in the Intensive Study Villages

Village	Category - I		Category II		Category III				Total
	0-5 acres		5-10 acres		Over 10 acres		Employed		
	No.	% of up to 5 acres	No.	%	No.	%	No.	%	
Gijri	43	48.2	10	11.2	0	-	36	40.4	89

COMMUNITY HEALTH PROJECTS: AT THE CROSSROADS ?

sumathi nair

Any number of alternative experiments in community health have come up in the last decade. This article takes a closer look at four such projects which have today become models for others. The article is not an attempt to run down any one or other project or its founder. Rather, it raises relevant questions about the contribution of these projects to health and development, their overall perspective, and the manner in which they are organised and administered.

The early 70's was a period for a general spurt in development activities of different kinds. This was the time when some of the major community health projects were started. It is over a decade now since they have been established and their effectiveness in achieving the goals initially set up is now under review.

A careful study of these projects would reveal various conflicting aspects which deserve deeper study. All these projects have, over the years, come to revolve around the founders, while the people centred thrust they had set out to achieve has not been realised. Yet their contribution to the field of community health cannot be denied.

The focus of this article is to try and analyse what led to the present situation — the limitations inherent in such projects and the other contributory factors. I must add that this article is not an attempt to run down any one or other project or its founder. Admittedly it is far easier to be analytical in retrospect, than it must have been to have visualised the pitfalls before the event.

For the purpose of this exercise, I will take four well-known health/development projects — Gonoshasthya Kendra (GK) Bangladesh, the Jamkhed Project, Maharashtra, the Deenabandu Project, Tamil Nadu, and the Comprehensive Rural Operations Service Society (CROSS) project, Bhongir, Nalgonda District, AP. My comments are based on personal experience, literature and personal communications.

Gonoshasthya Kendra (G K): In 1971 during the Bangladesh war of liberation, a few doctors, of whom Dr. Choudhary was one, set up a hospital for the care of the wounded, which moved into a rural area after the war and started a community health project in Savar, near Dhaka. This Peoples, Health Project is now funded by foreign donors. Today they have 65 trained paramedics (mostly women), nine of whom are village based. They undertake health work, run a school, pharmaceutical factory, a women's centre and have formed agricultural cooperatives. They are today sought after by the government and international bodies. for the health training they provide. GK has "arrived" — they have further plans for expansion.

Jamkhed : The comprehensive Rural Health Project was founded by Drs. Rajnikant and Mabel Arole in 1971 in Jamkhed, Ahmednagar Dist., Maharashtra in 30 villages (covers 60 villages now). They set up a project to deliver health care in rural areas, implementing the village health worker scheme, involving community participation. They also gradually included training in agriculture, provision of safe drinking water, employment schemes, nonformal education etc. They have been receiving some support from donors abroad. The Drs. Arole were given the Magsaysay award for their work in this field.

The Deenabandu Project : Drs. Prem and Hari John started their work in Deenabandhupuram some miles from Vellore in Tamil Nadu in 1972-73. They gradually shifted their focus from "help to all" — to helping the needy. A community health programme was started and village health workers were trained. They are supported largely by the organisation called World Neighbours. Here too, the doctors realised that ill-health had to be tackled in a broad and integrated manner taking all factors leading to poverty into account. They have, for this, started several programmes — economic loans, agriculture and animal husbandry, literacy classes etc.

CROSS : Founded by M. Kurien in 1975 with the intention of "empowering the poor", they undertook the work of organising the poor to fight for their rights. Starting with less than a 100 villages with funds from donor agencies abroad, the organisation has expanded today, to reportedly, 500 villages in and around Bhongir, in Nalagonda District of Andhra Pradesh. The programmes include providing economic loans, training in agriculture and animal husbandry, health and adult literacy, to the poorer sections of the villages. Their major achievement has been the formation of sangams for men and

women, in each village, where the problems they face and the programmes offered, are discussed. CROSS is today supposedly one of the leading development groups in the country.

The founders of these projects are all doctors (except for Kurien) who had been trained within the established medical system and yet had the vision to conceive of an alternative approach to health, one for which few models were available at that time. Besides, all these groups, spoke in terms of "community participation". It was perhaps the spread of leftist ideas at that time that influenced these non-political groups with the ideals of democracy and people's rule. Kurien and Choudhary, in particular, had connections with the communist parties of their countries. One therefore assumes that their notions of people's participation was based on a relatively better understanding of the rural situation and the power structures that operated within it.

The Drs. Arole and Drs. John, on the other hand, were more influenced by the christian missionary spirit and were thus keen on doing "service to the need" (John & John, 1984). To them people's participation had a different meaning. "We started his as a total community programme for the rich and the poor alike, for we believed we had a duty to all" (John & John, 1984). Similarily Dr. Arole, talking about their selection of Jamkhed says, "At Jamkhed the leaders made arrangements to provide accomodation for the staff of approximately 20 people..... . ..... The leaders also tried to understand the basic concepts of the project". (Arole 1980). When the leaders of a village are given such importance it is not likely that there could have been much participation by all sections in the village. Drs. John admit that they gradually realised that their understanding was not right (John & John 1984).

Despite their differences in background and approach to start with, all of the project holders realised gradually that health was not a matter of merely delivering medical services, it was closely bound to the poverty of the people, their lack of food. Gradually the programmes expanded to improving agriculture and economic backwardness through the granting of loans, setting up of night schools and women's groups. They made attempts to tackle the problems which, as they saw it, lead to ill health.

With the loans provided — at GK it was 100 taka per person at first with a 4 percent interest to improve his agricultural production — some of the village folk did manage to improve their living conditions. All the villages that were adopted by CROSS in its initial years have at least one well today, for general use. Training in improved agricultural methods, on all projects have helped some of the poor to make the best use of the little they had. The non-formal educational classes, on all projects, taught some of the village people to read and know where to put their signature and so on. Basic arithmetic taught to the women at GK have helped them as they said, to run their small vegetable vending business more efficiently.

It is in two particular areas however — that of health (except at CROSS) and women's development that there has been a great advancement. This can be seen in the lives of the women, who have been involved in the project, particularly in Savar, but also in the other project areas. Many women who have only known oppression have now come to look on their lives with greater hope and confidence. The excitement this knowledge has generated was seen in the literacy classes at GK in the fact that a woman health worker found the courage to stand for panchayat elections at Jamkhed and in the militancy of the women at Bhongir (CROSS).

In the area of health all the areas mentioned have in the last decade registered a fall in the IMR, immunisation coverage of mother and child is high, the family planning acceptance rate is also far higher than the national average and the maternal mortality rate has fallen. The number of 'at risk' cases are provided with regular care and in case of emergencies immediate care is provided by the referal system, where operations too are conducted.

The improvement in the health status and the status of women in these areas, are more or less, directly as a result of the programmes undertaken. This has been achieved through consistent hard work over the years, the training provided to the paramedics is quite thorough and they are very conscious of the great responsibility placed on them. Today if there was to be a test of skills in dealing with rural health problems at the village level, between these paramedics and city trained doctors, the paramedics would come out in flying colours.

Inspite of the benefits these development programmes have conferred on the people of the area anyone with some understanding of developmental issues, who visits any of the four projects mentioned comes away with a feeling of disappointment and disquiet. Before visiting GK, it was, for me, from all I had read, a model project in community health

with the people directly involved in the programme. I looked forward with great anticipation to seeing the project, only to be disappointed from the first few hours itself. The project has a 100 acre campus with two large multiple-storied structures on it. As I entered the campus, I was made to wait at the gate before being taken to one of the senior paramedics I knew, just so that my reference could be cross checked. The women gate-keepers were in uniform and were there to see that all and sundry do not enter the place. This by itself was shocking—such a clearly hierarchical structure and such control did not, in my mind jell with a democratic set-up. The rest of my stay only led to confirm this impression.

Centralisation of Authority

Perhaps the other projects do not have such structures but certainly from all reports, these other projects too have a tacitly functioning hierarchy, which is fairly rigid with the sole decision maker/arbitrator on practically all issues, being those at the top, be it a Choudhary, Kurien, John or Arole. No doubt it is these few who have had both the vision and the longest exposure to the work undertaken and hence have a right to a certain amount of decision-making. But what of the others who also worked along with them over the years? There appears to be very little of sharing in the process of decision-making. This almost total authority that they wield was once defended by one project director who said, "After all I get the funds, so its for me to decide what I do with it". Perhaps the others would not put it quite so blatantly, but in essence this approach operates in their projects too. Another director is known to have sent in a proposal for a new scheme without consulting his senior colleagues, who came to know of it only when a member of the donor agency mentioned it a year later!

The major danger in such autocratic trends is that of the centralisation of power. Every major and often minor decision needs an okay from the people at the top. This becomes particularly difficult as the project expands and the work increases, as has happened in all four cases. Not only do the individuals at the top have to work harder — which any one familiar with these projects is witness to, many of the decisions get delayed and several are not followed up. Often field level coordinators do not feel confident enough to take on a responsibility they will later have to answer for. At times issues instead of being settled at the village/cluster level, are brought by an individual directly to the chief so as to gain support for his point of view, before presenting it to the village sangam. In CROSS, for instance, the scope for such lobbying with the boss is immense. The "games of power", that eventually set in are in contradiction to the earlier vision of "community participation".

The trend described here is perhaps due to the lack of accountability the project heads enjoy. Maybe in the earlier phases of their growth they were accountable to their funders, or there might have been the danger of their funds being stopped. But as their fame and "success" increased they have now got a 'carte blanche" on funding. Often no major uncomfortable questions are asked of the project holders nor are any but the barest stipulations made of them.

The project holder is theoretically not answerable to the people whom he has set out to serve. The people are not told very much about programme budgets, policies, apart from what is necessary for their day to day functioning. Yet the project directors, particularly in the early years of their work, have shown a sense of responsibility to the rural poor, perhaps because of their basic idealistic motivation. Nevertheless there is very little the people can do about changing policies, today. They are not taken into account.

As for the lay public, they could not care less about what goes on at these projects. The Government of India, had an uneasy relationship with such organisations earlier but now seems keen on formalising it. Toward this effort recently it was announced that henceforth all foreign funds to such projects would require central government clearance. Even if this is implemented strictly, the way this money is spent would be entirely decided by the project directors. Thus these directors have the field to themselves. A method of operation which does not have an inbuilt system of checks and balances is very likely to lead to absolute control by those in charge. This is not very healthy for those around them or for themselves.

The same authoritarianism also makes the project directors hypersensitive to criticism. They have received such accolades from the press, both national and international and are proud of their achievements, so much so, that they will put up with little criticism. A group of doctors wanting to do a critical evaluation of the Jamkhed project in 1980 were very specifically told that their report would have to be okayed by Dr. Arole before it went to the press. Such behaviour is but a symptom

of the malady but this too proves harmful to the project in the long run.

Cosmetic Changes, Not Structural : Why?

It is true that in all these projects, it is clearly recognised that the prevailing ill-health is due to the socio-economic backwarndness of the area. As a result the project directors have become concerned about the general betterment in the living conditions of the people apart from providing health care. Yet these efforts in the form of economic loans, agricultural inputs etc. described earlier are only superficial, cosmetic changes which do not bring about structural change. At the most they temporarily lull some people into believing that "something is being done". In the long run as we shall see, they do more harm than good. The dependency of the target population on the project increases. Worse still, those among the poor who do get benefits from the projects, are envied by those who do not — this is as true of every one of the four projects described as of other such projects. In fact, this sometimes leads to village feuds. While at GK I was told of a case where non-beneficiaries implicated a beneficiary in a police case. The conflicts in the fragmented, caste ridden village situation thus get further aggravated by these efforts.

Such a superficial approach to the solving of deeprooted rural problems is particularly difficult to understand from people like Choudhary or Kurien who, considering their background, ought to have a clearer perception of the interplay of socio-political forces in society. One is naturally led to speculate on what could be the influences which result in this deviation from their original goal. Four possible reasons could be :

(1) Constraints placed by donor agencies — despite their easy relationship with donor agencies today, these directors must have had certain conditions laid down for them in the early days of their effort. Perhaps it was tacitly made clear, that any attempt at fundamental change would not be supported. For example, in the earlier phase CROSS did try to organise the rural labourers. Gradually this activity stopped or was sporadic, over a small area, with the director being careful not to be present on such occasions. The donor agencies could perhaps have had a direct influence on the petering off of the radical approach.

(2) The reason for sticking to cosmetic change could also be that the radical approach is too demanding, too risky to be sustained over a long period. Most workers within such organisations join for "employment" and a "living wage" and not because of their 'commitment to a cause". They are, therefore, not too willing to risk their lives for the villagers they are supposed to represent. This is not to say that it has never happened. One paramedic at GK was, in 1976, murdered by the local people who were opposed to the change he was trying to bring about. Possibly there are other minor instances of acts of courage in other projects too, but, as the years go by, one gets to hear of few incidents of actual struggles with the local powers. As mentioned earlier the risk to one's life and sustainance of the project, is too great.

(3) Thus we come to the next factor in this tie-up— that of the groups gradually taking care not to antagonise the forces in power. There even appears to be an understanding among the local power groups the police and these organisations that each will leave other alone. The status-quo remains and basic change fails to occur. There is the example of a coordinator at CROSS who, with the blessings of the director, employs unpaid bonded labour on his farmlands, while he gets a salary from the organisation, for the "upliftment of the poor".

(4) These experiences have not in any way led to any deeper analysis of the problems which these projects both face and create. Or if such an analysis has been made none of the projects have acted upon it. Just as the different departments within the government have come to function independently of each other, inspite of knowing the need for inter-departmental coordination, so too on these projects the directors have had to narrow down their efforts to chiefly providing health care and superficial changes or things would become too difficult for them. All efforts at radically changing the health situation, has to remain at the verbal level. One would find that since it is so, once these directors withdraw from the area, the health situation in 5-10 years time would most probably revert to what it used to be before the doctors took over.

Models Which Are Not Replicable

The next major issue, is that of the replicability of these projects. It is not possible to replicate any of them unless one is an Arole, John or Choudhary. Sheila Zurbrigg points out that the success of the Jamkhed project led the Government to implement the Community Health Worker (CHW) scheme at the Primary Health Centre level in 1978 (Zurbrigg, 1983). And this was, as is

established today, a failure — for one thing the "essential ingredient of the 'model' project — a relationship between village level health worker and his/her community based on trust, committment and accountability to the poor village families" — was missing. This led her to ask, 'If the essential relationship of a CHW approach is therefore doomed when placed within the caste-class structure of society, what possibility is there for effective broad replication of the locally successful 'model' project?" (Zurbrigg, 1983). Similarly the present medical education does not generate, in doctors, any sense of commitment to the poor or their health problems. The medical system too, on the whole does not cater to the needs of the rural areas, much less the rural poor. Thus any question of the replicability of such projects is moot.

Related to this is the growing dependence of the people in a project area. When a project like any of these gets established its continued effectiveness over a period of time becomes heavily dependent on the presence of the individuals who started them. None of the projects functions in a manner which will enable it to carry on as before if the 'leader' were not there. The people in the project areas become dependent on them and their sustainance depends on the project. Even the health workers are rarely allowed to work independently (though some senior paramedics do so, to a certain extent, at Savar). As Prem and Hari John admit, "Of course, two independent control mechanisms do exist in the programme, more to see the effectiveness of the VHW than to "supervise" " (Zurbrigg, 1983). This inability to give up control becomes a decisive factor in determining the eventual nature of the project. This is the tragedy, that inspite of setting out to establish a people's project, even after a decade of work, the people cannot, or are not seen as being capable of running their own project.

Together with this is the notion of self-sufficiency. There has been a time in all the projects where there was some talk of making the project self-sufficient. Initially, at CROSS the idea was that the economic loans given to the poor would be returned in full and with this pool of money thus generated, fresh loans, without outside help, could be made. This could be done in several areas and gradually the economic loans programme could become self-sufficient. But this idea was not seen through and gradually the talk of self-sufficiency died down. With so much foreign funds available so easily where was the need to learn to be independent?

Here it must be said that perhaps a health project is difficult to sustain without funds — as some others have learned to their cost. But it is not impossible (Werner, 1978). Even assuming that a certain minimum of funding is necessary, surely some attempt to generate it locally could be made? It is interesting to note that this notion of self-sufficiency does bother Drs. Prem and Hari John. They however manage to side-step it, though not very convincingly, by saying "We had this problem until we realised that "Self-sufficiency" referred to the project, while what we were aiming to build at the community level was "self reliance". We were working towards building community capability in health care and hence self-reliance" (John-John). How can a people dependent on a project that is not self-sufficient, be taught to be self-reliant?

Another trend manifest in these circles today is the development of jargon and "management" techniques. Thus CROSS has a management consultant on call to tell them about "systems analysis" and "strategy planning" and so on, to help alleiviate rural poverty — the old methods having failed perhaps the new will succeed. Terms like 'intersectoral integration", "integrated community" approach and so on are bandied about. They do this more, it would seem, to please the elite they interact with and the donor agencies, than to help solve any rural problem, for it is hard to believe that these founders still do not acknowledge that the essential question is one of sharing of power and its fruits by all.

What now ?

These projects have come a long way in the last 10 years — there were several points along the way where things could have changed for the better. But this was not to be. Now after having a positive impact on the health status of the people, their continued presence in the area is only likely to create fresh problems, as we have seen. It is time now that they either decided to gradually withdraw or radically change their strategy. The passing years have proved that these miniscule efforts do not really make any impact on the total health situation. They would be far more effective today if they undertake organising work among the rural poor and see that they demand that the existing government health facilities be made available to them.

Work and Health : An Alternative Perspective

Bharat Patankar and Jogen Sengupta

The "work and health" question (SHR 1:3) is a historically specific one. Its meaning has changed with changes in the social structure. There are societies which do not face this problem at all. All these aspects of the problem have to be considered in formulating strategy and action in today's context.

There were societies which did not face the question of "work and health". These were societies which "work" is not defined in state, class, patriarchal, race or caste terms. Their vestiges exsit today. Not only that but in them "work" is not regarded as "struggle" with nature or an attempt to master nature. When male and female human beings think of themselves as part of nature and live and act accordingly, they cannnot separate "work" from play or pleasure. Appropriating from nature external to them does not become a thing separate from lively and creative intercourse with it. So the risks, hazards and dangers could not be considered as "work and health" issues, but as part of the total life of human beings along with nature.

Work and life got decisively separated from and turned against each other only after patriarchal, statist and class domination emerged. Casteist and later racist domination became part of these. It is only from this point that human existence and the enrichment of it becomes seen as a struggle with external nature, an attempt to achieve mastery over nature. It is only in such societies that the problems of health becomes seen as one of "work and health".

In these societies the life of the majority is decided not by themselves but by the state, males, dominating classes, castes and races. Once "work" got separated from other life it became the first health problem, giving rise to unhappiness and a sense of subjugation. This alienation was the first and greatest problem of "work and health", causing basic ill-health whether work contains other risks, hazards and dangers or not. People working under such conditions could not feel that part, the work part, of their lives as their own. Or they internalised this ill-health and became dehumanised apart from the attempts of struggle they gave against these conditions. This major aspect of ill-health because of work will remain in our lives until the end of various hierarchical subjugations and alienations from remaining nature, no matter what changes take place in the technology. The nature of this ill-health has taken various forms depending on changes in the social structures.

Technoloy is not separable from the process of subjugation of the people who work with it. It is not free from the type of relations of humans with nature. Its structure internalises these relations. The particular kind of technology we are experiencing today which is destroying the ecological balance and creating disastrous health problems for people working with it shows these internalised social relations. The fight against ill-health and the hazards of "modern technology" cannot simply mean dislodging the ruling class which controls it but a fight against all the practices and social relations which structure it.

Patriarchy and the sexual division of labour create distinct health problems for women and children. This happens not only in the fields and factories but also in home work (which is not considered work at all in the male chauvinist culture). This problem of work is related not only to surplus value creation and technology but also to specifically sexual and patriarchal relations. Without a study of this aspect of "work and health" one cannot deal with the ill-health of a majority of the population.

Casteist social division and division of labour have been creating problems of health related to work for more than thousands of years in India. Apart from class divisions, these forced the majority (in some cases a minority) of the people to do work which obviously creates health hazards and traumas of all kinds. Today, even wrapped in capitalist relations of production on a wide scale, casteism and racism are creating specific problems related to work.

Class and state domination is both a part of this picture and a major factor in themselves creating ill health related to work. While it is true that these dominations are very much concerned about extracting surplus or surplus value, it is not the sole concern they have. Whether capitalists or the state will spend resources for reducing health problems at work also depends on their concern to maintain their continuing existence as dominating sections. At certain conjunctures they might even bear losses

or invest in "non-profit-creating" measures to maintain health in the long term interest of appropriating surplus or surplus value. Such actions might be deceptive for anyone who sees the picture only as one of "continuous greediness to increase surplus value no matter what happens with the workers' health."

Today the new movements of ecology, health and safety groups in the unions, workers' control and grass-roots democracy, various kinds of peoples' science movements, women's health groups and so on are bringing forward studies and practice helpful to this question. Many left groups are becoming conscious of this aspect and trying to act accordingly. These are important advances and close coordination of all the movements, unions, organ - sations of the rural poor community organisations, cultural organisations will deepen and extend this movement. It will be a movement that may start with efforts to reduce ill health in fields, factories and homes, but it has to fight to abolish class, state, caste, and patriarchal domination along with abolishing the technological monstrosities specific to these dominations. This only can establish harmony with nature and abolish "work" itself, the first and basic cause of ill health.

Need for Population Control Cannot Be Ignored

Vrijendra

The editorial perspective (SHR, 1:4) by Manisha Gupte does an excellent job of summarising the marxist critique of Malthusian view on the 'problem of population'. However, the perspective gives rather an incomplete picture of the situation. It is true that the ideology of population control, as preached and practised in the poorer countries of the world, is primarily used to divert attention from the real issues and factors behind poverty and other related aspects of life for a vast majority of people.

The perspective fails to adequately emphasise the well established fact that in the experiences of today's developed market economies, the changes in the family size and population structure since Industrial Revolution followed a rise in living standards of population. It was also significantly affected by a host of legal and institutional measures adopted by the goverment of the day as the needs and priorities of the ruling classes changed. This, of course, only enforces the view that population control is a consequence of the development process and cannot be a substitute for necessary strutural changes in a system where a tiny minority is the prime beneficiary of the process of development.

Another important aspect that should have been reflected in the perspective is related to the changes in the pattern of population growth in the centrally planned economies of Eastern Eurpe, USSR and China in the last few decades. One does not have to agree with the details of alternative systems there to recognise the effectiveness of medical system in these countries and its impact on their population growth.

The idelogical misuse of the family planning and population control by the ruling classes in various countries of the world should not detract anyone from the possible disturbing effects of continuing high rates of population increase in large parts of the world. Again, one does not have to be a neoMalthusian to say that, unlike the historic experiences of the developed market econmies which could afford the 'natural' adjustments in their population growth and structure spread over a long period, the world as a global entity has to take cognizance of the natural resources and their potential growth as well as limits to growth as the global population continues to increase. Family planning and population control must constitue an explicit objective of any meaningful strategy of development. Population control cannot be a substitute for development; development without measures to check population growth is not likely to be very meaningful either.

I am quite surprised to see the benefits of birth control and contraceptives only briefly discussed under the sub-title of 'the feminist perspective', as if there were no socialist perspective of birth control! I am sure the author views the feminist perspective as integral to the socialist perspective, but she fails to clarify that benefits of birth-control and contraceptives have much wider implications for the society as a whole and must be recognised as such, apart from their effect on sexual mores of the society.

Women, for obviovs reasons, are the direct (actual and potential) beneficiaries of the various methods of birth-control. They also are, as a result more prone to various, at times dubious, experiments in the field. But, quite surprisingly, again, the author has not even mentioned the the politics of number in relation to birth-control for men.

Another issue that deserves mention : I am greatly disappointed that a magazine like SHR does not have any leading feature on the health issues and the peoples' right to know potential and actual hazards to their health, associated with industries in which they either work or which are in the vicinity of their homes, except for a note-like article by Anurag Mehra. I am sure that despite your prior commitments, Bhopal tragedy deserves more importance than has been hitherto accorded. I hope your next issue on 'Health and Imperialism' will more than compensate for this omission and will also focus on the implications of this tragedy for the peoples' right to health and safety in addition to its other aspects rooted in the political economy of industrialisation in the poor countries of the world. And finally, hearty congratulations for timely production of SHR.

17 March, 1985.

Criticism of Tubectomies Unscientific

Anant Phadke

A frontal attack by Sucha Singh Gill in his *Politics of Birth Control Programme in India* (SHR I : 4) though not comprehensive enough, was very much needed. But he goes too far at the end of his article, and makes some very sweeping statements which can not stand a little deeper probing. The way he attacks and rejects tubectomies as a method of sterilisation is unscientific. It is superficial to criticise tubectomies by just saying that after tubectomies "back-ache, pelvic pain and other problems make the women chronically ill. In a survey conducted in Punjab, more than 80 percent of women complained of one or more problems after operation." There is a lot of literature on complications, complaints after tubectomies and it is widely known that many women wrongly attribute many of their health-problems, particularly back-ache to tubectomies. A survey merely reporting what women felt after tubectomies is too insufficient a basis for a sweeping criticism of tubectomies. A correct argument would be to point out that though incidence of complications due to tubectomies is not high in absolute terms, tubectomies should not be pushed when far more simpler and safer method of sterilisation is available for the male. Since the government and the medical system does not want to attack the patriarchy in the society, (they themselves help perpetuate it) it is pushing tubectomies, when in reality it should be used only in exceptional circumstances.

Gill's reasoning that birth control programme is "a serious attempt by the rulers to reduce the number of their enemies in order to reduce the risk to their oppressive regime" is quite off the mark. Increase in the number of pauperised population does not increase the chances of social revolution or even a revolt. It is the contradiction between developed capacities, aspirations of the people (as a result of capitalist development) on the one hand and their actual suppression (especially in periods of crisis) due to capitalist social relations that create possibilities of revolution.

Gill does not take into account the role of patriarchy in deciding the size of the family. The necessity of having male children; non-cooperation of husbands in family planning (both consequences of patriarchy) contribute to a larger size of the family even when women do not want more children. (In India every year, about half a million women undergo medical termination of pregnancy and about four to six million undergo abortion through unsafe methods which kill thousands of women every year. This shows that they many times do not want pregnancy.) It is true that unlike in middle and upper class families children in toiling classes do contribute to family's income. But they probably consume more than what they produce since upto the age of atleast three years they consume on an average, about a quarter (in terms of calories) of what adults consume without being able to contribute in production. Slightly older children look after younger children and spare adults for outside work. But the point is—was there a necessity of having this younger child in the first place?

High infant mortality and lack of old age security are the real justification of having a somewhat larger family The rest is due to patriarchy and ignorance about family planning. Let us not gloss over this and indirectly justify any unnecessary burden on women due to patriarchy, ignorance...

REVOLUTIONARY IN FORM, REACTIONARY IN CONTENT
A Critique of Ivan Illich

b ekbal

Ivan Illich's contribution to the analysis of health care and the Illichian school of thought which it has generated have contributed enormously to the strengthening of the basic tenets of bourgeois individualism. The school's very political basis together with its regressive solution to the problem make it reactionary in content. It serves the purposes of monopoly capital by promoting a victim-blaming ideology, an anti-technological mode of medicine in commodity form and advocating a tightening of the medicare belt. The article presents a marxist critique of the basic theoretical and political postulates of Illich. It is largely based on two articles, (Vicente Navarro's "The Industrialisation of Fetishism" in 'Medicine Under Capitalism' (Prodist) New York, 1976, and Howard S. Berliner's 'Emerging Ideologies in Medicine in 'The Review of Radical Political Economics' (9:1, 1977)).

In the last decade a number of books have appeared attacking clinical medicine in fundamental ways. Of these Ivan Illich's *Medical Nemesis* (Pantheon 1976) has received wide critical coverage in the popular as well as the academic media. Although Illich offers a highly informative and important critique of scientific medicine, in the final analysis he tries to suggest a reform of medicine along bourgeois ideological lines. This leads him to conclude that health is a function of our individual consumption pattern, that less medical care is better, so that working class would be better-off (healthier) in the long run by tightening their medical care belts.

The net impact of Illich is to serve the purposes of monopoly capital by : (1) Diverting attention from the economic sources of disease and collectively based response and advocating a victim-blaming ideology; (2) Undermining the petit bourgeois mode of medical care delivery leading to life style politics; and (3) Legitimising a cut-back of all forms of medical care services.

The Roots of the Crisis

There is no doubt that modern medicine is passing through a period of deep crisis in the developed countries outside the socialist block. The crisis of modern medicine reflects and is a part of the crisis of modern capitalism. Briefly, the cause of the crisis lies in the falling rate of profit due primarily to increasing variable capital costs (mainly wages and fringe benefits) not matched by increased productivity. Resumed accumulation requires the destruction of unproductive capitals and the diversion of variable capital (including social wages) towards new, relatively productive constant capital. Lowering variable capital costs involves both the diversion of labour and money away from the reproductive sector (health, education, labour, welfare) and the reorganisation of the reproductive sectors to place them more firmly in the control of capital. The health system has thus come under the scrutiny of capital to reduce those costs and help expediate the recovery process. An ideology which promotes anti technological (hence cheap) modes of medicine in commodity form is advantageous to capitalist's efforts to lower the costs of labour.

During periods of economic expansion and explicit class struggle, capital has been forced to provide greater medical care and preventive services for workers (raising its variable capital costs). As accumulation slackens the need to reduce those costs of reproducing labour heightens. As the costs of capital rise through expanding medical technology and through inflationary medical care reimbursement systems, without concomitant gains in terms of productivity, capital seeks to lower the level of health care provided. This struggle takes an added significance in a period of severe economic crisis.

Victim Blaming Ideology

As capitalism progresses and leaves increasingly dire health hazards in its wake, the technologically-oriented system of medicine tends to mask the origin of that morbidity by treating illness as an individual disorder through the use and purchase of commodities. Increases in disease morbidity and mortality and the increasing recognition that they are directly attributed to the capitalist mode of production cause concerns for capital on two distinct levels. It brings the legitimacy of capital into question at the point of production

as workers become more concerned about the effects of the production process on health, and it greatly increases the costs of providing medical care as workers spend more time off the job going through elaborate radiological, chemical and surgical therapies. The economic crisis exacerbates this struggle and thus capital tries to shift the responsibility for disease back to the worker—in this case through the promotion of victim-blaming ideology—and of individual solution for the worker defusing the class aspect of the morbidity.

Victim-blaming is not a new ideological response by capital. It has been used in education, welfare and even in health before. What is especially significant about this new wave is that, there is a chance that victim-blaming strategies may become the basis for public policy. In the west the popular media have been devoting a growing amount of space to life style changes and their positive contributions towards health. It is clear that this victim blaming epidemiology is getting wide circulation and acceptance.

Ideology of Industrialism

Illich is an articulate theoretician of the most prevalent and influential ideology used to explain our societies; i. e. the ideology of industrialism. The primary characteristic of that ideology is that the production requirements of the technological process and *Pari Passu* (at the same rate) of industrial organisations are the most important determinants of the nature and form of our western developed industrialised societies. In a fatalistic and almost deterministic way the former, the technological process, leads inevitably to the latter, the industrialisation of society. Moreover, according to the theorists of industrialism industrialisation has transcended and made irrelavant and *passe* the categories of property, ownership and social class. Indeed ownership loses its meaning as legitimisation of power. And control, now assumed to be divorced from ownership has passed from the owners of capital - capitalists - to the managers of that capital, and from there to the technocrats.

A final characteristic of industrialism is that it claims to be a universal process. In other words all societies regardless of their political structure, will evolve, according to the dictates of industrialisation. Indeed, according to a key component of that ideology, the theory of convergence, all societies will progress towards the urban industrial model of the future. Thus, socialism and capitalism are usually seen as two convergent roads to the same destination - the industrial model. Viewed in this way, the social problems of capitalist societies become not the problems of capitalism (an altogether *passe* category) but the problems of industrialisation.

Illich believes that industrialism is the main force shaping our societies and that unavoidable and irreparable damage accompanies industrial expansion in all sections, including medicine, education and so on. The industrialisation of medicine leads to the creation of a corpse of engineers — the medical profession — comparable to the technocrats of the main social formation of industrialised societies, the bureaucracy. Thus, the industrialisation of medicine means its professionalisation and bureaucratisation. And Illich believes that capitalism and socialism are indeed outmoded concepts since they are basically converging towards the same path of industrialisation that overwhelms and directs their social formations. In this interpretation, then, the class conflict has been replaced by the conflict between those at the top, the managers of the bureaucracies indispensable to the running of an industrialised society and those at the bottom, the consumers of the products — goods and services administered by those bureaucracies. As applied specifically to medicine, that conflict is the one between the medical bureaucracy, primarily the medical profession and medical care system; and the consumers, the patients. This antagonistic conflict appears as iatrogenesis (damage done by the provider) it is clinical when pain, sickness and death result from the provision of medical care; it is social when health policies reinforce an industrial organisation which generates dependency and ill-health, and it is structural, when medically - sponsored behaviour and delusion restrict the vital autonomy of people by undermining their competence in growing-up, caring for each other and aging.

How can we avoid and correct this iatrogenesis, the extensive damage done by the industrialisation of medicine? Before stating his own solution Illich briefly considers several other alternatives presently debated in political circles. In discussing solutions for clinical and social iatrogenesis, he especially rejects the socialisation alternative that he attributes to the equalising rhetoric of what are misleadingly termed the progressive forces among which he includes liberals and marxists. According to his normative conclusion, the redistribution of medical care implied in the socialisation alternative would make matters even worse since it would tend to further medicalise our population and create further dependencies on medical care. According to

Illich "less access to the present health system would, contrary to political rhetoric, benefit the poor". *In that respect Illich finds the creation of the National Health Services in Britain as a regressive not a progressive step.*

Instead of socialisation and its implied redistribution Illich recommends the following solutions for clinical and social iatrogenesis. The mode of production in medicine should be changed via its deprofessionalisation and debureaucratisation. He suggests that licensing and regulation of healers should disappear and concerns of where, when, how and from whom to receive care should be left to the choice of the individual. Collective responsibility for the health care should be reduced and individual responsibility should be maximised. Self-discipline, self interest, and self care should be the guiding principles for the individual in maintaining his health. In summary, each one should be made responsible for his own health.

As for the structural iatrogenesis, he again dismisses the alternative of socialisation and public control of the process of industrialisation, recommending instead the reversal of that process ie. breaking down the centralisation of industry and returning to the market mode. The essence of his strategy for correcting structural iatrogenesis, then is an anti-trust approach with strong doses not of Marx or even Keynes but of Friedman.

A major weakness of his evaluation is that he takes as an indicator of the effectiveness of medical care, indicators of cure. Indeed, he seems to confuse care, with cure. And in evaluating the effectiveness of medical care he does what most clinicians do; he analyses the degree to which medical intervention has reduced mortality and morbidity. In other words the effectiveness of health care intervention is analysed in terms of curing disease and avoiding mortality. But the limited evidence available indicates that medical care may reduce disability and discomfort in peoples' lives. For that taking care to occur, our medical care system would have to change very profoundly to better enable the system to provide that care. Still Illich does not seem to accept the possibility of creating another system in which the priorities would be opposite to those of the present ones, with emphasis given to care as opposed to cure service. Actually, Illich would not even welcome such a care-oriented system since it would increase the dependency of the individual on the physician and on the system of medical care, preventing the much needed self-reliance and autonomy.

Illich considers social iatrogenesis, the addictive behaviour of the population to medical care, to be the result of manipulation by the medical bureaucracy. He postulates that the consumer behaviour of our citizenry is primarily determined by its manipulation by the bureaucracies created as a result of industrialisation. The manipulation of addiction consumption and by bureaucracies (including medical care bureaucracy) is not the cause, as he postulates, but the symptom of the basic needs of the economic and social institutions of what he calls industrialised societies, the industrialised capitalist societies. Those bureaucracies, are the mere socialisation instruments of those needs ie. they reinforce and capitalise on what is already there — the need for consumption, consumption that reflects a dependency of individual on something that can be bought, either a pill, drug, a prescription or a car.

Actually those dependencies are mere symptoms of a more profound dependency that has been created in our citizenry not by industrialisation but by the capitalist mode of production and consumption - a mode of production that results in the majority of men and women in our societies having no control over the product of their work, and a mode of consumption in which the citizenry is directed and manipulated in their consumption of the products of their work. This dependency on consumption—this commodity fetishism—is intrinsically necesssary for the survival of a system that is based on commodity production. In the medical care system in capitalist system we find that (a) the alienation of the individual in his world of production leads him to the sphere of consumption of health services and that (b) the medical care bureaucracy is just administering those disturbances created by the nature of work and the alienating nature of the capitalist mode of production.

Illich finds structural iatrogenesis to be due to the culture of industrialisation. His solution for that iatrogenesis includes breaking down the industrial bureaucracies, and returning to self-reliance and enlightened self-interest. But by focussing on the medical bureaucracy as the 'enemy', Illich misses the point because those bureaucracies are the servant of a higher category of power - the dominant class. In the health sector power is primarily one of class, not of professional control. Indeed, the medical bureaucracy administers but does not control the health sector. We find then that the main conflict in the health sector replicates the conflict in the overall social system. And that conflict is primarily not between the providers and consumer, but between those that have a dominant influence in the health system (the corporate class and the upper middle class) who represent less than 20 percent of

(Contd. on page 100)

DUST HAZARDS IN COAL MINES
A Brief Overview

amalendu das

The global energy crisis of the last decade has provided an impetus to the development of coal resources which has, in turn, meant large scale indiscriminate mechanisation programmes. These have had disastrous consequences for the health of miners. The article highlights some of these health hazards which are being largely ignored by both the mining industry and the trade unions.

Of late the management of our nationalised coal industry has laid considerable stress on promoting the production of coal. And to achieve this end large scale mechanisation with borrowed foreign technology has been adopted. Critics from the Trade Union front have correctly identified the drawbacks of such a plan of reckless mechanisation. Lack of employment generation, high overhead cost that erodes the benefit of the economy of scale, dependence on foreign countries for spare parts of the machines are the important aspects of their criticism. But one important consequence (perhaps the most vital one) of reckless mechanisation seems to have escaped the attention of all concerned. This is the problem of health hazard which is increasing at an alarming rate.

It is unpalatably true that hazard has been synonymous with the term coal mining in India. The risk of fatal disasters to which the coal miners are exposed to is as great today as it has been during the days when coal mines were owned privately — Chasnala (1975), Jitpur (1978), Hariladih (1983) disaster. The introduction of sophisticated machines has in no way reduced the chances of such accidents. But that is a different story altogether. Here the attention is intended to be drawn towards that kind of hazards which silently, slowly and steadily shorten the life span of the miners, or make them physically disabled even when there is no massive disaster in the mines.

Coal mines are inherently unhealthy places to work. Not only in underground mines, but also in open cast quarries where giant earth movers are used, the workers inhale large amounts of dust, fumes and gases which cause many killer diseases - mainly respiratory in nature. They include influenza, asthma, emphysema, stomach and lung cancer, hypertension, Pneumoconiosis and bronchitis. The most fatal of all respiratory diseases is Pneumoconiosis commonly known as black lung disease which is incurable. (See SHR : I : 3, December 1984).

It is caused by the inhalation and retention of respirable coal mine dust in the lower lungs. A noticeable dose-response relationship usually appears when exposure continues for a decade or so. Coal worker's pneumoconiosis is classified into levels of ascending severity from simple to complicated by X-ray diagnosis. Continuous dust exposure can accelerate a case of simple pneumoconiosis to more advanced stages. Miners with progressive massive fibrosis are usually totally disabled. If the dust concentration is still higher, emergence of pneumoconiosis is earlier. Some miners seem to be more vulnerable than others and this vulnerability is yet to be explained. Habit of smoking appears to have no significant role in causing pneumoconiosis among the miners. It certainly contributes to lung impairment to a miner as it does to any non-miner. It has been established with a fair amount of certainty that it is dust, be it coal or otherwise, which can cause pneumoconiosis among the miners. So dust is identified as the greatest hazard.

Dust may be looked upon as suspended solid contaminent in a state of minute subdivison present in the air. It is produced during various industrial activities like blasting, grinding, drilling and crushing or whenever any material used in industry undergoes disintegration. Such operations enhancing the occurance of dust are too common in coal mining industry. As the material undergoes progressive disintegration it acquires certain properties which has killer significance with regard to health of those exposed to its action. The very minute size (0.2-10.2 microns) itself confers it high reactivity both chemically and biologically and it becomes more toxic than its parent lump from which it has been disintegrated. These tiny particles once air borne can neither be swept off nor trapped by existing technical means. It is estimated that one cubic meter of a coal lump, after progressive disintegration may form 10^{12} particles and eventually spreads through 283 million cubic centimeter of the working environment.

Because of its small size these dust particles do not settle down and remain suspended in the air for quite long time.

It is quite natural, therefore that the various operations at the mechanised coal mines not only generate more dust but they reduce the size of the dust particles to a minimum. And these tiniest particles are more dangerous. Scientists have estimated that particles which are retained in the alveoli, the gas exchanging sacs of the lung – weigh 5 micrograms or below. These particle are termed as respirable dusts.

Generally the larger particles (nonrespirable dust) do not penetrate the alveoli and are not thought to cause pneumoconiosis. While the distinction between respirable and nonrespirable dust is scientifically valid, it is clear that both sizes can impair lung functions when inhaled in quantity over time. The larger particles are probably linked to bronchitis among the miners. Although these particles are generally not retained in the lung, continuous exposure to them during normal work year produce more or less constant irritation of the upper respiratory tract. Breathlessness has also been found to be significant among miners who do not show X-ray evidence of pneumoconiosis. Researchers believe the breathlessness is related to chronic non specific obstructive pulmonary disease. Some investigators have found, in addition to pneumoconiosis and broncho-pulmonary disease, a third as yet unidentified disease process that reduces the ability of the lungs to exchange gases.

Black lung disease has come to represent a broad definition of occupational respiratory disabilities in miners of which coal miners' pneumoconiosis (henceforth referred as CWP) is one major component. Respirable dust which is invisible to the unaided eye accounts for less than one percent of the dust in a mine. It is not clear how much nonrespirable dust is retained in the lungs when the standards for respirable dust (if they exist at all) are being met.

Along with CWP, coal miners will continue to experience other lung diseases — bronchitis, severe dyspnoea (shortnesses of breath) and airways obstruction. Many of these illness are work-related. Coal mine dusts contain a wide range of non-coal constituents including silica and naphtalenes. Researchers have found as many as 13 Polynuclear Aromatic Hydrocarbons (PAH) in the respirable mine dusts they had studied. (Shultz, Fridel and Sharkey, 1972). PAHs are tested carcinogens. Besides trace elements that are mentioned above there are a host of other elements listed as 'hazardous elements which are liberated as dust or gas in the place where coal is cut from the working face. These hazardous elements are identified as Arsenic, Beryllium, Cadmium, Fluronine, Lead and Mercury. It is worthwhile to mention here that a mine producing one million tons of coal generates one ton of each element annually. These elements may have a role in producing black lung disability either alone or synergestically. They may also play a role in the excess lung and stomach cancer found among the coal miners.

Diesel powered equipments are commonly found in all the mechanised coal mines throughout this country. Diesel engines produce emissions that are known to be hazardous, unburnt hydrocarbons, oxides of nitrogen, particulates, PAH, phenols, aldehydes, oxides of sulpher, trace metals, Nitrogen compounds, smoke and light hydrocarbons many of which cause adverse respiratory effects.

Noise is a proven hazard to the miners working in a mechanised mine. Noise may cause temporary or permanent loss of hearing sensibility, physical and psychological disorder, interference with speech communication or the reception of other wanted sounds and disruption of job performance. Excessive noise may also cause changes in cardiovascular, endocrine, neurolgic and other psychological functions. Studies on the subject indicate that coal miners have miserably worse hearing than the average.

CWP and other work related disease in coal mines have been recognised as the subjects of large-scale investigations in countries like USA and UK and this recognition came through relentless struggle of the workers themselves. A physician Dr. Lorin Kerr who is also the representative of the coal miners of America voiced his alarm against CWP "At work, you (coal miners) are covered with dust. It is in your hair, your clothes and your skin. The rims of your eyes are coated with it. It gets between your teeth and you swallow it. You suck so much of it in your lungs that until you die you never stop spitting up coal dust. Some of you cough so hard that you wonder if you have a lung left. Slowly you notice you are getting short of breath, when you walk up a hill. On the job you stop more often to catch your breath. Finally just walking across the room at home is an affort because it makes you so short of breath. (Kess, 1968.)

We do not have any Dr Kerr to lament for our miners. Our miners are not even aware of such a fatal disease. As the detection of CWP is difficult in the initial stage without powerful X-ray examination (the facilities for which is non-existent in our colliery hospitals) the miners who suffer from shortness of breath or exhaustion are often wrongly treated.

The author has encountered several such cases in the Jharia coalfield. Kripal Chamar of Damoda Colliery has been treated as a TB patient because he has been suffering from shortness of breath. Kripal was told that TB is a curable disease but he wonders why in his case the medicine does not work. Another miner Chanari Beldar of Kenduadih Colliery died of TB(?) two years ago. When this trouble of breathlessness began Chanari used to abstain from his work once or twice a week. He received charge sheets and warning letters for negligence of duty. No one bothered to enquire about the real causes of his illness and consequent abstenteeism. We do not know the exact number of miners who suffer from breathlessness or other similar symptoms of CWP among Indian coalminers. But certainly the number is not small. Even in technologically advanced countries where more effective dust control methods are used and where people are more aware of such diseases, the number of miners affected by CWP is quite large. It was estimated that in USA between January 1970 and December 1977, 4,20,000 coal workers were awarded Federal Black Lung compensation because of total disablement due to CWP. In UK, National Coal Board had conducted a survey during 1974-77 and found that seven percent of the British coal miners were suffering from CWP. In India a small scale study conducted in 1960-66 by the Chief Advisor of factories revealed that 178 (18 percent) of 2754 coal miners who were radiologically examined were suffering from CWP. Another random representative survey done by Dr Viswanathan in 1964 showed the incidence of CWP varied between 6.0 to 16.8 percent. The situation here in India is certainly alarming.

Last decade witnessed a global energy crisis caused by price-hike of petroleum resources coupled with impending depletion of the same and this resulted in reemergence of coal as vital alternative. Eventually its scale of production was raised, mines were mechanised with borrowed technology associated with heavy over-head cost in terms of foreign exchange but a thing which was conveniently forgotten is the probable environmental impact.

Legislations, covering mines safety fail to address the problem related to miners' health and welfare. It appears that miners' health and welfare as an entity distinct from mines safety is yet to be recognised. It is equally distressing to note that established trade unions with commendable fighting spirit while realising economic demand are yet to recognise this invisible monster—the fugitive dust which slowly but steadily, surreptiously advances forward to collect its toll among the miners. Now the question is who will cry a halt?

of the population and control most of the health institutions, and the majority of the population (lower-middle class and working class) who represent 80 per cent of the population and who have no control whatsoever over either the production or the consumption of those health services. To focus then as Illich and majority of social critics do, on the conflict between consumers and medical providers as the most important conflict in the health sector, is to focus on a very limited and small part of the actual class conflict.

One of the functions of the services bureaucracies - including the medical bureaucracy - is to legitimise and protect the system and its power relation. One aspect of that protection is social control — the channelling of dissatisfaction which Illich introduces as structural iatrogenesis. But to believe that social control is due to the culture of medicine and the pervasiveness of industrialisation is to ignore the basic question of who regulates and most benefits from that control. An analysis of our societies shows that the service bureauracies — including the medical care ones - although willing accomplices in that control, are not the major benefactor. The ultimate benefactor of any social control intervention in any system is the dominant class in that system.

In short the major suggestion of Illich for solving our problems is self-reliance, self-care and autonomy of the individual - what can be described as lifestyle politics. This philosophy strengthens the basic ethical tenets of bourgeois individualism. Moreover, the lifestyle approach to politics serves to channel out of existence any conflicting tendencies against those structures that may arise in our society. The strategy of self-care assumes that the basic cause of an individual's sickness or unhealth is the individual citizen himself, and not the system and therefore the solution has to be primarily his and not the structural change of the economic and social system and its health sector. Contrary to what Illich and others postulate, the greatest potential for improving the health of our citizens is not primarily through changes in the behaviour of individuals, but primarily through changes in the patterns of control, structures and behaviour of the econmic and political system. The latter could lead to the former. But the reverse is not possible. Actually, it is precisely because of the impossibility of the reverse, and thus the lack of conflict between Illich's message and the basic tenets of the capitalistic economic system that his message, the lifestyle politics is and increasingly will be presented by the organs of the media as the resolution of our crisis and problem.

BOMBAY-400 039.

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved.

Each issue of the journal will focus on one theme, but it will also carry (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

Our forthcoming issues will focus on : Systems of Medicine, Mental Health and Health Care in Post-Revolutionary Societies.

If you wish to write on any of these issues do let us know immediately. We have to work three Months ahead of the date of publication which means that the issue on Systems of medicine is already being worked on. A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing style of reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. These need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be neatly typed in double spacing, on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions **in a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are working on issues of interest to you.

The People

(Excerpts)

Pablo Neruda

That man I remember well, and at least two
centuries have passed since I saw him :
he travelled neither on horseback nor in a
carriage — purely on foot
he undid
the distances.
carrying neither sword nor weapon
but nets on his shoulder,
axe or hammer or spade;
he never fought with another of his kind –
his struggle was with water or with earth,
with the wheat, for it to become bread,
with the towering tree, for it to yield wood,
with the walls, to open doors in them,
with the sand, constructing walls
and with the sea, to make it bear fruit.

I knew him and still he is there in me

. . . . . .

. . . . . .

Where he lived everything
a man touched would grow :
the hostile stones,
hewn
by his hands
took shape and form
and one by one took on
the sharp clarity of buildings
he made bread with his hands
set the trains running,

. . . . . .

. . . . . .

I think that those who made so many things
ought to be masters of everything.
And those who make bread ought to eat !

And those in the mine should have light !
Enough by now of grey man in chains !
Enough by now of the pale lost ones !
Not another man will go past except as a ruler
Not a single woman without her diadem

. . . . . .

. . . . . .

Someone is listening to me and although they
do not know it,
those I sing of, those who know
go on being born and will fill up the world.

WHITHER OTHER SYSTEMS OF MEDICINE ?

India, like other ancient civilisations of the world, had several highly evolved and sophisticated systems of medicine long before the advent of the so-called modern or allopathic system. Historical forces, such as the Greek and Muslim migration into the subcontinent, brought with them yet other systems which flourished and grew, with a mutually beneficial cross-fertilisation of ideas and techniques. Alongside these 'formal' systems of Ayurveda, Unani and Siddha (formal in that they had written treatises and established universities for teaching and training), was the rich, varied and location-specific lore of folk medicine and folk psychiatry, based on local plants, herbs and belief systems. Tribal medicine, and the home remedies of 'Ajji cha batva' (grandmother's purse) fall into this category. Another vital source of indigenous health care were the traditional midwives or 'dais', who not only performed the important function of birthing, but also abortions, in addition to advice and aids for contraception.

There is considerable controversy regarding the role of these systems and their practitioners in history, and indeed about the impact of the arrival of western medicine on them. Some scholars argue that the latter was primarily responsible for the atrophy and decline of traditional medical systems, even stating that the British sought to systematically destroy them on the grounds that they lacked 'scientific' bases and were filled with superstitious nonsense and positively harmful remedies. Others feel that this is too simplistic a view, and that some of these systems were in decline long before western medicine arrived on the scene.

This indicates the need for critical research into the social history of the pre allopathic systems of medicine. We need to understand their interaction within the socio-political context of different historical periods. What, for instance, was their ideological framework, and how did this reflect contemporary socio-economic and political structures ? The question of 'scientificity' is also often raised. But it can be established that even pre-allopathic systems were scientific, if the term means posing questions, seeking their answers through methodical study (using the means available at the time) and accepting a thing as true only if the same result is repeatedly derived. But this spirit of enquiry and experimentation seems to have gradually declined. Why this happened, whether it was the lack of concurrent technological development to facilitate it, or due to socio-cultural, economic and political forces, is what must be determined.

In this context, it is worth considering exactly how one measures the role of a given medical system, and how one assesses whether it has declined, remained or grown. One must address this question at two levels : first, at the level of theory. What is the extent and nature of growth of the theoretical base, both in depth and breadth, over a period of time? Second, at the level of practice, are the practitioners of a system growing in number, and hence the number of recipients of that type of care?

Evidence shows that upto Independence, the availability of allopathic treatment was largely limited to the cities and towns, and that too mainly to the higher socio-economic groups. If this was the case, then certainly the practice of other systems was not seriously affected since the majority of people, especially the poor, continued to rely upon them. But at the level of theory, the 'formal' systems at least seem to have suffered from stasis and decline, and perhaps because of the following two reasons : one, state patronage by Indian monarchs, which had provided the chief source of support for theoreticians and researchers, was not forthcoming from the British. Two, the growing intellectual domination of western science and thought, especially among the Indian elite, reduced the legitimacy and credibility of nonallopathic systems.

This situation did not change drastically even after Independence. The commitment of the post-Independence leadership to 'modernising' India, to promote (Western) science and technology in the country, and to provide 'modern' health services to all, ensured that state patronage would continue to be given to allopathy, whose practitioners had by then become a powerful lobby alongwith the pharmaceutical industry. Only the residue of the Swadeshi movement, and those leaders (like Gandhi) who were fervent advocates of indigenisation, ensured the allocation of some limited

resources for the development and strengthening of other systems of medicine.

Notwithstanding this, the status of traditional systems is fraught with confusion and subject to periodic swings. The major trends, however, seem to be the following:

The 'synthesis' school of thought which argues that the best of each system—including allopathy—should be studied and combined to create a 'National System of Medicine' (this manifests the heavy influence of the Chinese model). The 'purists' feel that this is both impossible and fatal to the future of traditional medicine. Fatal because it would result in the irrevocable decay of the non-allopathic systems, since allopathy would dominate both theory and practice; and impossible because the conceptual frameworks of the different systems are inherently incompatible, and thus they cannot be studied or evaluated using an alien methodology. Each system must be left severely alone to go in its own direction. Still others argue that the whole question of 'system' is irrelevant; what is needed is a safe, effective and affordable range of therapeutics for use in mass health care. If traditional medical systems have useful remedies which fit the bill, then they should be utilised without recourse to philosophical arguments. Finally, the 'modernists' within traditional medicine feel that the only way to restore their legitimacy is to apply the techniques of modern science to research and standardise these therapies and remove the cloak of mysticism from about them.

These differing and sometimes warring schools are scrabbling for a slice of an already minute cake. The last four decades have witnessed the growth of a plethora of indigenous medical schools, professional bodies, and research centres.

At the same time, these indigenous institutions, their teachers, students, researchers and administrators, generally suffer from an inferiority complex vis-a-vis their allopathic brethren. A 'keeping up with the Joneses' syndrome thus develops, based on the rationale that by acquiring the characteristics of allopathy, the indigenous systems will regain recognition. One example of this is the widespread use of allopathic drugs by indigenous practitioners, made possible by the relatively easy availability and rapid action of these drugs. Non-allopathic practitioners argue that with the spread of and exposure to allopathy, people have become impatient with the slower-acting indigenous therapies which, if properly prescribed and taken, demand more from the patient (like dietary and life-style changes) than allopathic treatments. This is also an interesting comment on the marketing strategies and ethics of the allopathic pharmaceutical industry. Another sign is the 'me too' phenomenon in the growing indigenous drug industry, which is developing, producing and marketing non-allopathic drugs and pharmaceuticals at a rapid rate—particularly vitamins, tonics and restoratives.

Therefore, while the indigenous medicine infrastructure is larger and stronger than it was at independence, it suffers from the same diseases which afflict modern medicine in India—commercialisation, mystification, professionalisation, rising costs and curative bias. The only difference, perhaps, is that its controlling elite is more fragmented and less cohesive in its functioning and goals.

What, then, is the role of the various indigenous system in a people's health system? Should they all be clubbed together or does each one have a distinct and separate role? And what of Homeopathy, another imported system which has taken firm root in India and provides an important alternative especially in urban areas? Obviously, all these questions must be researched and cannot be fully answered at this point, but we can review existing information to throw some light on them.

For instance, it is useful to look at the ways in which people actually utilise these different systems (where they are available) at grassroots level, to see if these use-patterns provide some clues. A few studies of this type were undertaken in the 'fifties and the 'sixties in Punjab, UP and Karnataka. Interestingly, most of them found one common thread: people's use of alternative health care sources was highly rational. By and large, allopathy was used for acute conditions and for those diseases where it offered known cures—such as TB, malaria, and infectious diseases. Ayurvedic, Unani and herbal treatments were sought for chronic ailments like skin diseases where these systems offer far more effective therapies than allopathy. And home remedies or folk cures were resorted to for simple self-limiting complaints like colds, coughs, diarrhoeas and fevers. Of course several factors like cost, distance, attitude and behaviour of the providers influenced (perhaps more strongly than cure-effect alone) the choices people made. But essentially, the strengths, weaknesses and relative benefits of each system seem to be perceived quite clearly by people.

Unfortunately, there is a growing feeling (though little documented evidence) that this situation has undergone considerable change in the past decade or two. One of the main reasons is the greater penetration of allopathy into rural areas as a result of the overproduction of MBBS doctors who find private practice unlucrative in the saturated city market and opt for rural areas as comparatively profitable. This phenomenon has resulted not only in increased availability of allopathy in the rural private sector, but also an exposure to its rapid-fire remedies. Thus more and more people have been 'hooked' onto treatments which are either wrongful applications or overuse of valuable, even life-saving interventions. The prime examples are the preference for injections over oral medication and the demand for overnight cures which bring their own costs through widespread drug-resistance and toxic side effects.

What then are the tasks ahead of us if we wish to rid indigenous and other systems of medicine of their present ills and make them part of a radical people-based health care system?

First and foremost, it is clear that no changes within these systems nor in their role in health care can occur without corresponding changes in the role and nature of allopathy. The battle on both these fronts must be based on similar strategies : major structural changes in the socio-economic-political system which controls and shapes (or distorts) all of medicine and health care.

Within the health care sector, the following steps would then perhaps bring us closer to the goal : first, demystification and popularization of all medical knowledge, regardless of system. This may in fact be easier with traditional medicine, whose basic concepts are closer to people's beliefs and health culture than those of modern medicine. Second, the trend of professionalisation must be reversed. Since a significant part of indigenous therapeutics is based on herbs and dietetics, they lend themselves to decentralised cultivation, production and distribution. Axiomatically, the commercialisation of traditional drugs and pharmaceuticals, particularly for producting useless vitamins and tonics, must be stopped. This should only be permitted where the economy of scale and geo-climatic limitations favour centralised production, and that too for really useful remedies which are needed for mass health care. This will keep indigenous medicines within people's reach, and discourage the growing consumerism which is being cultivated by vested interests in order to market phony, expensively-packaged medicaments. Finally, a massive re-education of the people is necessary to wean them from dependence on the rapid-fire cures which unscrupulous practitioners (especially of allopathy) have used to win their faith.

Finally, there is one more important issue which must be examined with reference to indigenous systems of medicine : the question of gender bias. Sexism in indigenous systems is a completely uncharted area which demands exploration. Much has been written about the gender-biases in the theory and practice of modern medicine, but how do other systems view women? This question must be studied at three levels : 1) Is there a gender bias in the conceptualisation of women's health and disease in other systems? 2) Is there a sex-distinction in their therapeutics and in the delivery of care to women? and 3) Is there discrimination against or decimation of women practitioners of indigenous systems, including folk and tribal medicine? And if so, are pressures arising from within the system, or from the spread and influence of allopathy?

There is an urgent need to study these questions and, if necessary, sensitise non-allopathic systems to the special health problems and needs of women. This is all the more crucial since traditionally, popular medical knowledge and wisdom was largely the preserve of women, but this rich resource is being eroded and lost. Organised medicine systematically discredits it, without offering an adequate substitute. Thus women are losing their traditional source of self-care (especially poor women), but with nothing to replace it but a growing dependence on a health system which throws them its crumbs.

In this issue, we present articles which focus on the debates and controversies about traditional medicine, its role and relevance. Dhruv Mankad attempts a dialectical analysis, using the Chinese experience as an illustration. Sujit Das and Smarajit Jana's analysis presents a contrasting view. Ravi Pathak describes the grass-roots practitioners' perspectives. We have also reproduced two articles from *Social Science and Medicine*, Roger Jeffrey's which gives an historical account of the policies towards indigenous healers, and Catherine Mac Donalds' which examines the political economy of traditional systems. In addition, we present Anant Phadke's article which looks at the role of doctor's

organisations in the context of their recent struggles (this article was held over from the previous issue). We hope these articles will stimulate further discussion and research.

A DIALECTICAL APPROACH TO TRADITIONAL MEDICINE

A Lesson from the Chinese Experience

dhruv mankad

The main protagonists in the debate on traditional medicine are the 'traditionalists' and the 'modernists'. The former argue that traditional medicine was suppressed by the colonising powers and should now be revived; the latter feel that traditional systems are inherently inferior to modern medicine which is more 'scientific' and therefore the best choice for the future. But both views, the author contends, are rooted in contradictory philosophical standpoints, and attempts to find a dialectical approach, using the history and development of Chinese medicine as an illustration. The discussion is in three parts: the first critiques both standpoints and contains a general discussion of the dialectical approach; the second and third parts attempt to illustrate the concrete application of this approach in Chinese medicine.

Extensive debates, often eluding any resolution, have been going on especially in the erstwhile colonies, regarding the exact status of traditional medicine as a science. On the one hand it is argued by the 'traditionalists' that traditional medicine has been suppressed by their respective colonisers and this has led to its decline. It should be extended institutional as well as financial support and developed further. On the other hand, the 'modernists' argue that modern medical science has made tremendous strides in knowledge regarding the human body, its diseases and their treatment. Thus, they consider it naturally superior to traditional medicine. The former reject modern medicine as being culturally alien and hold traditional medicine as having exclusively developed within the culture and thus the only appropriate system of medicine (cultural relativism). The former favour development of modern medicine only, as being the only scientific medicine devoid of any cultural and ideological factors (neutralism). Both views are rooted in two contradictory philosophical standpoints.

In this paper, we shall endeavour to identify the two standpoints, analyse them in the light of the nature of scientific knowledge and find a dialectical approach to this problematic; using chinese medicine as an illustration.

The paper is divided into three parts. Part I deals with general questions on the nature of scientific knowledge and analyses the two standpoints mentioned above and contains a general discussion on a dialectical approach to this problematic. Part II and III deal with the concrete application of such an approach as seen in the development of Chinese medicine. Part II deals with the historical background and philosophical basis of medical science in People's Republic of China and socio-economic and political determinants informing upon its development, while Part III deals with the current implication of the policy of combining western and traditional medicine in the People's Republic of China.

I. Nature of Scientific Knowledge

Like any other science, medical knowledge too, has not developed in a unilinear, orderly, from a lower to a higher level evolutionary fashion, but its history reveals a zig-zag path of development interspersed by many breaks and jumps. In other words, science, instead of developing from a primitive level to its modern state by a careful, logical, screening of available 'objective' facts and later rejection of those not found to be true, has, having proceeded in one direction, taken an entirely different path later. No direct, internally consistent logical connections may be found between these paths. The essential aspect of these breaks and turnabouts has been the transformation of world-views, the sudden shifts in the attitude towards nature and the man-nature relationship. That is to say, these breaks are essentially philosophical in nature.

These breaks were the consequence of a struggle between different, often contradictory schools of philosophy. In this struggle, the school which fulfilled the ideological needs of the ruling class dominated the rest.

Now, if science is defined as a rational body of knowledge gathered by human beings during the social production of their material (and non-material) conditions of existence, then science (not with a capital S—the modern bourgeois science having an absolutised abstracted existence in the capitalist society) has been with human society since its very

inception. So has been medical science. An outgrowth of animism, wherein all diseases were seen as a result of inflictions of evil spirits, it was one of the earliest sciences. Human being's intercourse with nature produced on the one hand empirically verifiable facts having an objective existence, and a universal truth value. It also produced various concepts, thought categories and logic specific to natural science with which these facts were organised and various levels of generalisations were achieved. These specific thoughts, categories and logic are influenced by thought categories and logic of thinking process in general. That is to say that they are rooted in philosophy. In fact, for a long time science was indeed a part of philosophy.

Now, at different points in history, both in time and space, this non-cognitive component is influenced by different cultural and ideological factors and is thus shaped differently. This may even result in establishment of different "facts" in different cultures. (Here one is disregarding the question of validity and truthfulness of these 'facts'). Thus, for example 'geomancy' the chinese science of wind and water which determines placement of house and tomb with respect to features of landscape and aesthetics of land use, has no counterpart at all in western science (Elzinga and Jamison, 1981). The development of both the facts—the content and the concepts, thought categories and logic with which they are organised—the form—takes place in an interpenetrating, dialectical fashion, each deriving support from the other. Many a times the development of facts comes into sharp conflict with the concepts leading to either transformation of the concepts themselves or to distortions of facts by ideological rationalization of the conceptual form. What happened to Ayurveda in India during the Medieval period was the latter. The anatomical, pathological and pharmacological insights gained by generations of experimenting physicians were distorted by the use of concepts like Karma Siddhanta, divine will, and transmigration of souls etc. On the other hand, the scientific revolution of the 17th century Europe was an example of the former when entirely new forms of logic was developed by Comte, Descartes, Bacon, Newton and other philosopher-scientists.

While the ideological rationalization of Ayurveda suited the purpose of the Brahmin-dominated, varna-jati based feudalism in a decadent state, the scientific revolution in Europe was in response to the growing strength of the European commercial and industrial bourgeoisie.

Thus the factual component and the conceptual component of scientific knowledge exist in a dialectial relationship, under constant tension and under the influence of ideological and other factors operative in the culture and the historical period of its orgin.

This view is debated from two standpoints, positivist and cultural-relativist.

Positivist Standpoint

The basic tenet in positivist philosophy is that the scientificity of a proposition lies in its anchorage in empirical statement of facts. Therefore, the central part of a positivist programme is to build a theoretical structure which is understood in term of its interlinking with empirical statements. It does not allow for any hypothesis which cannot be or has not been verified empirically and objectively. This absolutisation of empiricity and objectivity results in a narrow delimitation of what can be called a Science. In particular, theories operative in premodern knowledge producing practices such as alchemy or Ayurveda that does not match upto some piece of modern science, falls outside its realm. They are not even considered as hypotheses yet to be verified.

Francis Bacon advocated a ruthless rejection of old 'idois' inherent in all the preceding knowledge systems but his methodology reinforced all of them by absolutising the objectivity of scientific knowledge. The attitude of positivism towards all the other knowledge-producing practices can be summed up, in his own words :

"It is idle to expect any great advancement in science from the superinducing and engrafting of new things upon old. We must begin from the very foundations, unless we would revolve forever in a circle with mean and contemptible progress" (Bacon, 1620).

This fetishism of facts has had the obvious consequence of converting science into scienticism with the metaphysical principles of objective consciousness basing itself in an alienating dichotomy of observing subject and observed object, the invidious hierarchy of nature which places man at the top and legitimises an experimental inquisition of nature, ... the mechanistic imperative that says that everything that can be known should be known and that such knowledge should be utilised regardless of consequences (e.g. genetic engineering unnecessary and unethical human

experiments —DM), the extension of instrumental domination of nature to man himself" (e.g. excessive reliance on medical technology in health care) (Elzinga and Jamison, 1981).

Such a perspective when applied in medicine means that those traditional medical sciences which have not adopted the positivist principles of objectivity are considered unscientific. The theoretical concepts and prescribed therapies of these sciences not having been tested under the modern, laboratory –'Controlled'—conditions are rejected as invalid. Concepts like acupuncture points or tridosha in Ayurveda, which have no counterpart in modern medical science, are considered as non-existent. Even when, as in the case of acupuncture points, the functional if not the anatomical existence of a point, is demonstrated, it is not accepted. Thus the most 'advanced' scientific mode of enquiry into nature ends up by denying nature ifself if it does not fit into its theoretical straitjacket.

Cultural Relativist View Point

From the other end, the opposite view point considers that the general concepts of sciences, the value promoted by them and the 'ideal' of what constitutes valid and proper knowledge differ from culture to culture. The cultural relativisits argue that modern science is the cultural artefact of the west while ayurveda, astrology and others are oriental sciences. Thus, every science is considered to be an ethnoscience, having a theory, a logic and verification techniques of its own, specific to itself and thus, incommensurable. For example, they argue that the efficacy of ayurveda must be assessed by the principles laid down in ayurveda only i.e. on its own terms, and not on the terms dictated by modern science. They rule out any 'objective' assessment standing outside the premises and logic of ayurveda. They point out that "it is only when domination over nature is considered the highest ideal for civilization that we find western science becoming the universal standard for measuring the achievement in all the other cultures. However if we take the unity of man and nature as a predominant positive value, the Chinese and other cultures' scientific tradition stand out as more advanced". (Alvares, 1979).

While sympathising with the eagerness to do justice with the achievements of pre-modern societies including those of Egypt, China and India, one must be wary of the dangers of slipping into an extreme form of such relativism—a position denying the basic equality of human experience and universality of certain scientific findings independent of geographical and cultural factors. Though it is true that science and technology of various civilisations should be understood on their own merits and not as abortive developments towards modern western science or worse as mere fiction, one must be cautious of how one formulates this point. "There is a danger ... of denying of the fundamental continuity and universality of all sciences. This could be to resurrect the ... conception of the various non-European civilization as totally separate, immiscible thought patterns ... a series of different views of the natural world, irreconciliable and unconnected." (Needham, 1954).

Thus, from the opposite end, the relativist view reinforces the positivist view that pre-modern and non-European sciences are different from modern science and thus incompatible. They differ only in their views regarding the relevance of these sciences. The positivists consider them as unscientific and thus irrelevant, while the relativists maintain that each are relevant only in their own culture.

This assumption of a basic incommensurability also implies that one must deny the contribution of these cultures to the universal body of knowledge, which is international. It also imparts a closeness to knowledge, the boundaries being limited by the culture. In fact, modern science is 'ecumenical', in the sense that historically speaking science is a product of diverse cultures and thus a common property of human kind. Secondly, this assumption denies any possibility of mutual exchange, thus legitimising elitist doctorines in each of these sciences. It also rationalises the doomsayer's conservative prophecy depicting modern science an uncontrolled and uncontrollable monster causing all the wars and social ills of our time. The only alternative such a view of modern science leaves is a total withdrawal into inner reality, an escape into 'privatised mystical experiences' aimed to create an 'inner' revolution. Thus, positivism and cultural relativism absolitise and/or universalise the form of scientific and technological development without considering the social context and the content of the various stages of its development

A Dialectical Approach

A dialectical approach to the problematic assumes that a) all knowledge is universal and humankind's common property; b) no scientific theory or methodology is perfect or unchanging and thus 'inherently' superior; c) science develops under the influence of a philosophical basis

generated within the framework of various socio-economic, political and cultural factors in interaction. Therefore, even though direct comparisons may be difficult, because theoretical systems in each cultural setting were different, nevertheless mediated comparison is possible.

This could be done "by testing out the theories of traditional sciences in the light of modern concepts, without absolutising the latter and by studying how and how much the former had succeded in discovering natural processes and in putting them in service of humanity" (not in order to achieve mastery over nature or human beings but for the benefit of all). Such a view opens up a possibility of integrating western and traditional sciences and a mutual exchange between the two. Having evolved under different historical and cultural conditions each embody different sets of strong points and limitations. The aim of such an integration is to reinforce each other's strong points and do away with the limitations.

Such an integration can contribute to the advancement of human knowledge in three ways:

— regional traditions embody useful concrete techniques, for example traditional herbal and mineral remedies that work without the side effects of many chemically manufactured drugs.

— regional traditions preserve an important body of data which can serve as a base for furthering existing fields of modern scientific research — examples are records of astronomers and meteorologists.

— regional traditions can open up new perspectives and avenues for modern scientific research, as in the case of acupuncture which has stimulated international neurophysiological research. (e.g. work on mechanisms of pain inhibition) (Elzinga and Jamison, 1981).

Such an endeavour demands a change in the world view and in the attitude towards history of science.

Only a dialectical understanding of the history of science, its relationship with philosophy and social context can produce the required 'break'. Such a conscious re-evaluation of the history of science also reveals a different future vision of an integrated science, wherein all the pre-modern and non-European sciences would find that their legitimate contributions have transformed the existing scientific knowledge and in turn have transformed themselves.

The most widely discussed illustration of such a process is Chinese medicine. A change in the implicit world view of existing medical science—both modern and traditional—led to an integration and development of both the sciences. The most notable product of this development is acupuncture. In order to study how this happened we shall briefly trace the history of Chinese medicine.

Historical Background of Chinese Medicine

Chinese medicine is one of the oldest known medicines. Very little is known about its origin but like stone age medicine elsewhere it must have begun as a primitive medicine. Archaeological evidence shows that the earliest inhabitatnts of the Yellow River Valley were people of the Stone Age and like the religious beliefs of other tribes of Stone Age, animism and demonology must have been the characteristic feature of their religion. We may safely 'assume' that they believed in the spirits of the dead, and worshipped natural events like thunder, rain etc. Their medicine too must have consisted of witchcraft, sacrifices and oblations. The situation changes later, during 1200-300 B.C. when their religion enters the age of philosophy. From being direct and immediate response to the multifarous problems including illhealth faced by the primitive being, it enters a stage where the Chinese human being has formed a metaphysical view of the universe, of man and nature relationship. Medicine too is influenced by this change. Witchcraft gives way to institutionalised medicine using processed drugs. It is seen that during the Chou dynasty, (1100-250 B.C.) physicians incharge of internal medicine, surgery and veterinary medicine were appointed (Wong, 1979).

The oldest legendary figure in Chinese medicine is Shen Nung (2757 B.C.) who is venerated as the father of medicine and is considered to be the inventor of drug lore. The oldest treatise extant is *Huang Ti Nei Ching Suwen.* (Yellow Eineror's Inner Classic). Though *Nei Ching's* period is around 2000 BC, the treatise is supposed to have been written around 200 BC. It is believed to have been written by several anonymous authors over the period. It is a theoretical exposition of the basis of health and illness, closely related to the cosmological ideas taking shape during the philosophical period. It lays down the basic principles of anatomy, physiology, etiology of diseases and their treatment (Wong, 1979).

Chinese medicine begins to assume a rational, scientific character during the Han dynasty (200 BC-220 AD) with Tsang Kung, Chang Chung King and Hua To as central figures. Tsang Kung lived

around 170 BC and left records of personal observation of twenty five clinical cases. Chang Chung King's treatise of fever marks a new era in Chinese medicine. He has described many types of fevers including typhoid fever in this treatise and it contains one hundred and thirteen prescriptions. With this treatise, the diseases were studied more from clinical standpoint—signs and symptoms, course of an illness, treatment and actions of a drug rather than from the point of view of the theories of diseases as was the case during earlier period (Kuttumbiah 1971). This transition shows that a scientific outlook was permeating medicine in the grips of speculative philosophy.

The third important text is *Pen Tsao* which describes useful plants, animal and mineral substances and their applications. Unlike *Nei Ching* it is a practical text and has undergone many additions over the centuries as the experience of the Chinese physicians of using herbs and minerals accumulated. This period saw a great intellectual flowering in China. Confucius and Han Fei belong to this period. Though a surgeon, Hua Tu is claimed to have discovered anaesthesia and to have performed some major and minor operations like laparotomy, venesection etc., this aspect of medicine had fallen into neglect during the later period for reasons discussed elsewhere.

Although the pharmaceutical traditions of *Pen Tsao* expanded, the *Nei Ching* remained less emendable because of its classic and semireligious status. Both, the Chinese feudal rulers and the physicians themselves looked upon it as a divine gift. After the Han dynasty, this resulted in Chinese medicine, becoming not stagnant, but backward looking toward the sources of classical antiquity and hence continuing to develop within the thoretical framework based on the philosophy of that period.

This backward-looking character of Chinese medicine made it particularly vulnerable to the cultural aggression of the imperialists during the 19th century. During the rule of various imperialist powers overwesternization was stressed and rivalry was set up between Chinese and Western medicine. Maligning the former as unscientific and a 'stumbling block' to the development of modern medicine they barred practitioners of traditional medicine from city hospitals and medical colleges. The Kuomintang government in 1929 put forward measures to aboish Chinese medicine. Among these were "restrictions on the practice of medicine by traditional physicians, a ban on setting up schools of traditional medicine and on publishing books and periodicals on Chinese medicine" (Li and Tsai, 1977).

It was in the face of Nationalist Blockade, during the liberation war, that efforts were made by the Chinese communists to utilise the locally grown herbs. In 1940, when liberated zones were established, this pragmatic step was taken up as a conscious policy of utilising indigenous medicine. (Liberated Zones were those areas in China where the Communist-led Revolutionary Committees had usurped political power from the Kuomintang government). This policy received official recognition when Mao Tse-Tung in his famous speech in 1944 at the Yenan conference on culture and education, urged the doctors to work with and elevate the scientific level of traditional practitioners in order to better serve the people (Mao., 1965). However, after liberation in 1949, the communist government continued to have traditional practitioners as auxiliaries to the modern medical forces. The directive of unifying the two systems of medicines was probably interpreted as giving the traditional practitioners some training in modern medicine. It was only in 1955, when efforts were made by the communist party to raise the status of traditional medicine. Traditional doctors were brought to city hospitals and clinics. Special wards were set up for acupunture and herbal medicine. Modern doctors were urged to learn from their traditional colleagues.

By 1958, thirteen new colleges for traditional medicine were opened. Over 50,000 students apprenticed themselves under distinguished traditional physicians. In 1955, a well-equipped Chinese Medical Research Institute with both modern and Chinese doctors on its research staff was setup. The entire body of knowledge was to be investigated.

In other words true integration of the two systems of medicine at theoretical as well as practical level was the goal.

The praise and support to traditional medicine reached its acme during the Great Leap Forward (1958-59) period. This period was characterised by over-enthusiastic policies of collectivisation of individual agricultural plots, formation of communes etc. This resulted in a reduction in the production of foodgrains and led to subsequent famine in some areas. With the retreat of its extreme policies, emphasis on traditional medicine also declined. Although the policy of combining the two kinds of medicine showed some triumphs notably in the

fields of resetting of fractured limbs using mobile splints, (Sheng, 1977) no major theoretical breakthrough towards a new synthesis was in sight.

With the advent of Great Proletarian Cultural Revolution, traditional medicine again came to the forefront. This period was probably the most turbulent one in the contemporary history of China. In 1966, the Chinese youth led by Mao, rebelled against dogmatism, bureaucratism and elitism of sections of the Chinese Communist Party, the government and other institutions. With the decentralisation drive, provinces and communes assumed responsibility of health services. Self reliance was the official policy, which meant depending upon local resources which often in rural areas meant traditional medicine and using locally grown herbs. Since then, by using combined traditional and modern medicine, many breakthroughs at both theoretical as well as applied level, have occurred especially in acupuncture analgesia, treatment of deaf, mute and blind (Chen 1973) and in nonsurgical treatment for conditions normally requiring surgery (e.g. perforated peptic ulcers) using acupuncture and traditional herbal medicine (Wu, 1977).

Thus, it should be noted that the introduction of modern medicine in China was not as a consequence of a natural transition from traditional Chinese medicine nor was it as a result of any 'inherent' superiority of modern medicine.

(It should be kept in mind that modern western medicine in 1929 when Kuomintang sought to suppress the traditional Chinese medicine, had in its therapeutic armentarium a few herbal tinctures, like Belladonna and Gum Acacia, few mineral preparations like Arsenic and Mercury and dangerous procedures like purgation and leching.) It was forced upon the colonial people. Ideological struggle has played a dominant part in the development of medicine everywhere and in China in particular.

This raises an important ideological question as to how the dominant philosophy of Chinese communists could reconcile with that of the traditional Chinese medicine. The answer lies in points of congruency between the philosophical basis of Traditional Chinese medicine and the Chinese interpretation of the dialectical materialist philosophy.

Philosophical Basis of Chinese Medicine

Chinese medicine assumed a scientific character in a period characterised by flourishing of great schools of philosophy: legalism, Confucianism' Taoism, Yin-Yang and five element school and Naturalism. Developments in medicine have been influenced by all of them to some extent, but its scientific theory owes a great deal to the last three.

Although differing in many ways over their general world-views, there are certain common points regarding man-nature relationships, in all the philosophical schools of this period. Man is conceived of not as a master of nature nor as its slave but as an integral part of a cosmic system having harmony and order. Confucianism admits a hierarchy of heaven-man-earth where all the human and earthly events are willed by heaven which imparts to it harmony and order. In other schools, motive force of the cosmic order is considered as spontaneous internal self-movement rather than mechanical impulses from outside. This tendency to analyse phenomena in dialectcial logic is reinforced by the Chinese language, it is claimed. Rigid 'A or not-A' categories are avoided (Needham, 1976).

According to ancient Chinese philosophy, in a healthy body there should be free flow of *Chi* (the basic principle of the entire universe) which is governed by the interplay of two opposite forces, the *Yin* (negative) and the *Yang* (positive). Disease results from their imbalance. *Yin* and *Yang* themselves evolved from nothingness which was the grand beginning of the Universe. Quantitative transformation of *Yin* into *Yang* or vice versa causes change.

Yin and *Yang* subdivide into five elements—water, fire, metal, earth and wood. Since the human being is conceived of as a product of Heaven-accumulated *Yin*, and Earth-accumulated *Yang*, the human being too, contains the five elements. *Yin* and *Yang* are not considered to be absolute and static.

The *Yin* and *Yang* concept is an example of conceptualisation in terms of contrariness, unity and transformation of opposites. One contemporary Chinese author maintains that dialectics in ancient China dealt with the interinfiltration, interdependence and mutual supplementation of Yin and Yang, the opposites of a contradiction .. (and) self adjustment of the system, which keeps the whole organic .... structure dynamically balanced. The keynote of the five Elements theory is that there is *Yang* in *Yin* and *Yin* in *Yang* functioning together and that, therefore neither of them alone can generate new things. (Li Zehou 1980).

Thus, like dialectical materialism, the philosophy of traditional Chinese Medicine, too deals with transformation, contrariness and unity of opposites. The Chinese medicine operated within such a conceptual framework. And with this concept, it sought to analyse and explain various observations regarding the human body, its diseases and their treatment. The only tools available to them were their five senses and the accumulated experience. This limits the validity of the empirical evidence available in support of such theoretical concepts. Now, the support or its refutation, is sought by intergrating the traditional Chinese medicine with modern medicine. Its analytical and experimental techniques as well as its empirical methodology is to be utilised for the purpose.

Generally, the philosophy of traditional Chinese medicine encouraged scientific enquiry. But historically, as Chinese medicine has come under the influence of different schools of philosophy at different times and places, its progress has not been a smooth one. For instance, under the influence of Confucianism, the official philosophy of the feudal ruling classes of China, Chinese medicine degenerated into dogmatism. For, although all the philosophical schools conceptualise the contradictory nature of reality, they differ greatly in tackling this contradiction. Confucianism propagates balance and harmony –the unity of opposites, Taoism opposition and revolt—the contrariness of opposites, and Legalism transformation of harmony into disharmony and vice versa in a cyclic fashion. Each world view represents a class ideology, with Confucianism being feudal, the ruling class ideology during the classic period (Elzinga and Jamison 1977). "Confucianism blocked the germination of new ideas and hamstrung the development of ..... scientific discoveries in China ....." (Ren Jiyu 1980).

To understand how and why this process took place we shall have to go into the socio-political factors which influenced the rise of Confucianism, its subsequent pernicious effects on the development of Chinese medicine as well as the overthrow of this ideology.

Socio-Economic and Political Factors Influencing Development of Medicine in China

In the last section we saw that the traditional medicine in China was developing under a theoretical framework under the influence of Confucianism, Taoism and Naturalism. But it was Confucianism which set its stamp on it. Confucianism stressed balance of opposites in a contradiction thus legitimising the stability and order of the feudal hierarchy in Chinese society. It was the official ideology of the feudal state, with the result that new ideas which could disturb this balance were not encouraged and scientific enquiry was stiffled. "This backward trend was due primarily to the decaying feudal relations..... But stifling effect of Confucianism on man's urge to explore also contributed to the virtual halt in the march of science ..... That feudalism held on so obstinately in China must be accounted for in part by the drawbacks of Confucianism" (Ren Jiyu, 1980). In concrete terms, it meant that analytical and experimental techniques not only did not develop but were looked down upon because they involved a work of manual nature quite like that of artisans who were considered low down in the feudal social order. For the physician to attain any social prestige and economic rewards, he had to be identified with the clasicially learned literati who constituted the social and political elite in feudal China. A similar situation existed in medieval India also (Chattopadhyay, 1977). The prestigious Confucian doctor was not a physician in the real sense because he acquired the necessary knowledge by reading medical classics and treated others only out of humanitarian motives. Full time medical practice as a profession was considered unworthy of gentry status and mandarinate. Yet amongst the ordinary folks, many practitioners continued to base their medical practice on experience and direct observation.

This has had all the adverse conseuences for further development of medicine. It not only retarded surgery a messy business which even medieval European physicians left to lower class barber-surgeons, but also inhibited the development of supportive physical and biological sciences. (Crozier, 1973).

Thus it was no wonder that the radical movement that developed in China after World War I, rejected traditional medicine as a part of decadent feudal culture and society. Ever since then, traditional medicine, its rejection or its support, has become a political issue in China.

Several factors led to it being restored to a prestigious position. Firstly, having been faced with Nationalist blockade in the Liberated Zones, Chinese communists were forced to rely upon the traditional practitioners for medical care. Moreover, in the struggle against feudalism, traditional practitioners as artisans were considered allies of the proletariat

and the peasantry. Having gained some useful lessons during this period, the Chinese Communist Party after the liberation applied them in practice. There was an extreme shortage of trained medical personnel and traditional practitioners were too important a human resource to be rejected outright. Moreover, traditional medicine, after having been shed of its feudal ideology, was put forward as a symbol of national heritage. In the struggle against imperialism, this played an important part in rallying the people around the communists.

During the Great Leap Forward, when there was a drive to demystify technical expertise, traditional medicine with its folklorist features was particularly suited for the purpose. With 'mass line' (the term used by the Chinese communists to denote their stress on the wisdom of the masses—the peasants and the workers) in ascendency, scientific knowledge was not considered to be a monopoly of highly educated. During the Cultural Revolution too with its anti-expert political line, modern medicine associated with its western trained specialists came under severe attack and traditional medicine of common folk-peasantry got a new boost.

Thus, the traditional physicians have now been reinstated to a prestigious position. They are encouraged to study modern medicine and along-with their modern counterparts, to undertake research in various aspects of traditional medicine, using modern scientific methods.

In concrete terms, the integrated medicine now being practised is drastically different from either its original classical form or the conventional modern medicine.

III. Current Status of Medicine in China

Restoration of traditional medicine for the Chinese never meant rejection of modern medicine. Modern medicine continues to dominate all the aspects of medical care. In medical care, training and research, modern scientific methodology continue to be applied but now traditional theoretical and practical diagnotic and therapeutic knowledge is sought to be integrated with it.

For the Chinese "combining Chinese and western medicine does not simply mean addition of the one to the other and certainly not replacing Western Medicine... by (its) native counterpart or vice versa. What is meant is the organic combination of the two medicines filling the weaknesses of the one with the strong points of the other raising the level of both, eventually evolving a new medical science incorporating the best features of both" (Li and Tsai, 1977).

Integration in Medical Practice

In medical practice throughout China more resources are now allocated to traditional medicine. Special wards have been constructed in the existing hospitals and new clinics have been set up. The traditional doctor now has a major role in OPD and with no loss of reputation is now calling for x-ray films and laboratory investigations, and when needed, western consultation Grey, 1971).

Rural health centres are staffed by both the traditional and modern doctors both of whom having received some training in the other system. There is considerable co-operation between them in day to day practice.

Barefoot doctors rely heavily upon traditional therapeutics including acupuncture. A barefoot doctor's manual lists around 533 traditional medicines. (Sidel, 1973). Reports indicate that model hospitals (usually Red Army hospitals) stress combined use of both the systems. One hospital reported that since 1969, 70 percent of the cases were treated in this way (Crozier, 1973). Diseases claimed to have been treated in this fashion include jaundice, pulmonary tuberculosis, inflammation of kidney (nephritis), inflammation of veins (phlebitis) severe burns, facial paralysis and fractures.

The most spectacular results by using combined traditional and modern medicine are in conditions where previously surgery was required, for example in perforated peptic ulcer (a condition where due to interaction between the inner lining of stomach and the acidic juice therein, there is first a small ulcer on the inner lining of the stomach, which may later burst to become a hole through the stomach wall with gastric juice sprayed over into the abdominal cavity causing severe inflammation of the abdominal lining). In such a patient, complaining of severe pain in abdomen, the modern doctors ascertain the part affected and the kind of disease the patient has by careful history taking, clinical examination, x-ray and laboratory investigation. "The ability to accurately determine local pathological changes is the advantage of Western medicine's method of diagnosis. Where it falls short however, is in understanding and analysing the functioning of the patient's body as a whole." (Wu, 1973). The Chinese doctors then ascertain the general status of the patient by traditional

method. After a careful study, a method has been developed using traditional and modern indicators like temperature and pulse and so on to judge the size of the hole and extent of fluid exuded. If the hole is considered to be large and fluid abundant, then the patient is operated upon, otherwise he or she is treated with acupuncture and herbal medicine. (Wu, 1973).

The other prominent breakthrough achieved by using the combined methods is in the field of acupuncture anesthesia and treatment of fractures.

Theory and practice of acupuncture has undergone significant changes as a result of self-evaluation on the basis of modern scientific concepts. Older theories and principles not verified in practice have been relegated to secondary importance. For example in diagnosis and prognosis, greater emphasis is placed on effective acupuncture points and their relationship to the autonomic nervous system and less on the theoretical aspects of Yin-Yang, the meridians and the Five Elements (though the latter are not entirely rejected.) (Chen, 1973).

Thus, in late 1950's Chinese medical workers reviewed their experience of acupuncture in relieving toothache and sore throat. They applied the experience to replace anesthetic drugs in minor operations like tooth extracticns and tonsillectomy and achieved some success. The technique gradually improved with more points being discovered. Now success has been achieved with placing needles only on the ear, nose and face (Chen 1973). Many major operations like abdominal and chest surgery have been performed using accupunture anaesthesia.

Another achievement has been in the field of treating deafmutism and blindness, using acupuncture (Chen 1973). Traditionally certain points were considered forbidden for deep insertion. But experiments showed that deep needling of these points produced return of the power of speech and hearing. Acupuncture therapy is combined with high quality speech therapy.

Acupuncture has also been used successfully in treatment of toothache, tonsillitis, jaundice, epidemic influenza, voice paralysis and polio (Chen, 1973).

Similarly, in the field of treatment of fractures, combined therapy is found to be superior (Sheng, 1977). The fracture is diagnosed using X-rays. The broken bones are realigned using acupuncture anasthesia. Then, the fracture is managed by tying standardised bamboo splints used traditionally around the fracture site. Quite unlike the extensive immobilisation method of modern orthopedics, this method advocates combined rest and movement. This has resulted in better healing, and greater recovery of function, particularly of old, complicated fractures. The time of immobilisation is also greatly reduced.

No discussion on Chinese medicine today can be complete without the mention of prevention and treatment of mental illness in China. Quite unlike the western method based on Freudian thinking, the psychiatric care in China is based on the belief in man's ability to change given a sympathetic environment and education and re-education' (Sidel R, 1973), (Ho, 1974).

Since the Cultural Revolution, with increased emphasis on integrating traditional medicine, the western trained doctors have altered their psychiatric service to include traditional methods and political techniques. The methods currently in use are self-reliance, collective help, drugs, acupuncture, heart to heart talks, follow-up care, community ethos, productive labour and teachings of Mao. Thus the process involves hospital and community care, individual and group relationships, professional and nonprofessional help, mutual help and self-reliance and traditional and Western medicine. Here again one clearly sees a tendency to avoid stressing on either of the opposites.

Integration in Medical Research

Scientific research in China is guided by four principles (Stuttmeir 1973) (1) Research must serve production and solve practical problems generally. (2) The indigenous, social, economical and intellectual — both contemporary and traditional experiences must be tapped. (3) Research must involve the masses and should not be a monopoly of the professional elite. (4) It should be an integral part of Chinese way of life. Struggle for scientific experiment, struggle for production and class struggle are considered three major tasks of a revoluntionary society. Medical research too, derives its orientation from the above principles.

The most outstanding feature of medical research in China is the concept of systematic co-operation built around small research projects. Research units having common interests work together regardless of their affiliations. For instance, production of new antibiotic 'Qingdmycin' according to the New China News Agency, was a result of combined

efforts of 36 agencies. The central body responsible for the medical research in China, the Chinese Academy of Medical Sciences maintains linkages with 24 different research institutes. The research areas include various specialities in the medical field like epidemiology and microbiology, surgery, pediatrics, pharmacology; areas in community and social medicine like environment. nutrition, labour hygiene, labour protection, occupation health, basic sciences like Medical Biology and traditional sciences like acupuncture, moxibustion and Chinese medicine.

Research in traditional medical sciences is organised under the Academy of Traditional Chinese Medicine. Its areas of research include medicine, surgery, acupuncture and pharmaceutics. The diseases studied successfully include asthma, bone fractures, high blood pressure, tuberculosis of bone, leprosy etc. (Stuttmeir, 1973). The unique feature of this Academy is the inclusion of western trained doctors in its research staff who have undergone training in traditional medicine. In 1966 there were around 200 such doctors out of a total research staff of 300 (Stuttmeir, 1973).

Another notable feature of medical research in China, is the combined use of traditional and modern diagnostic and therapeutic principles. In one instance 10 patients having a skull fracture with a large blood clot under the skull bone were selected on the basis of severity judged by modern diagnostic methods including x-rays. Then they were treated with intravenous mannitol and Chinese medicine. Conventionally, the blood clot would have had to be removed surgically. But this clinical trial showed that 9 patients recovered fully, the blood clot having been absorbed (Qiu Xiang et al, 1981).

Medical research also includes exploring the scientific basis of acupuncture. Based on extensive observation and research, it has been found that generally meridian system of traditional acupuncture corresponds with the neural pathways. But modern knowledge of anatomy and physiology of the nervous system cannot fully explain the theory of meridians. For example, on stimulating certain parts of limbs with heat, corresponding areas of the ears become sensitive to pain. Certain other unexplained physiological changes induced by acupuncture have also been demonstrated. For example, putting a needle through certain points in the body of a normal person causes increase in the number of white blood corpuscles and enhancement of the process of devouring of wastes and bacteria by these white corpuscles. Hormones too may be playing a part in this process in which different levels of the central nervous system have been found to be involved. (Chen, 1973).

What is most revealing about the philosophical aspect of medical research is that dialectical principles are often used in achieving solution of a research problem. For example from the principle "the law of unity of opposites is the fundamental law of the universe" in the words of a Chinese doctor ' we drew a number of conclusions : immobilisation and movement are equally important, fracture healing and functional recovery ought to be mutually complementary ... None of these aspects should be stressed to the neglect of the other. On this basis we formulated... new principles for the management of fractures" (Sheng, 1977).

Conclusion

Medical science developed in China under the influence of conflicting world-views, which represented the ideological requirements of the ruling classes or sections thereof. This struggle between contradictory philosophies was reflected in the sudden changes in direction which characterise the uneven course of development of medicine in China. Factors other than those intrinsic to science, played an important often determining role in shaping its course. The medicine that emerged after a conscious policy of integration was applied, reflected a change in the dominant worldview to one which is more organismic as opposed to mechanistic—a world-view implicit in bourgeois science.

Science and philosophy, two dialectical poles of a knowledge system, develop in an interpenetrating, mutually dependent fashion under the influence of the socioeconomic and cultural-ideological factors operative in a particular mode of production during a historical period. As Engels put it :

"Natural scientists... are still under the domination of philosophy. It is only a question of whether they want to be dominated by a bad fashionable philosophy or by a form of theoretical thought which rests on acquaintance with the history of thought and its achievements. Only when natural science becomes imbued with dialectics will all the philosophical rubbish.... be superfluous disappearing in positive science" (Engels, 1976).

Only a conscious appraisal of the history of medical science keeping in view the above perspective can provide a future vision of a new Intergrated Medicine.

In this way by emphasising equally empirical observation and dialectical concepts, on positive science and dialectical philosophy and by combining the traditional and modern medicine, Chinese medical science has contributed significantly to 'humanity's broad onward march.'

POLICIES TOWARDS INDIGENOUS HEALERS IN INDEPENDENT INDIA

roger jeffery

Policies towards indigenous healers in independent India show considerable continuities with policies followed in the British period. varying according to the sex of the healer. Traditional birth attendants (dais) have been offered short periods of training by the State since 1902, whereas until recently male healers (vaids and hakims, and later homoeopaths) have been treated with official hostility. Current plans include the training of religious and ritual healers in psychiatric services as well as the employment of indigenous healers in new community health schemes. These changes are assessed in the context of a political economy of health services. This article is reproduced from 'Social Science and Medicine' 16:1835-1841, 1982.

Introduction

Many discussions of the potential role of indigenous healers in health systems ignore the historical dimension, apparently assuming that the proposals are novel and practicable. No-one should make this mistake in India, where there is the work of Leslie and Brass to draw attention to shifts in policy from 1820 onwards.[1] In this paper I want to elaborate on a small part of this topic by looking at official policy with respect to indigenous healers in the context of theories about the dynamics of relationships between indigenous and cosmopolitian medicine.

There are, in essence, three views of these relationships in India. The first is the naive scientistic: that the process is one in which the indigenous systems are steadily giving ground to the onward march of science, with only the areas where Western medicine is ineffective remaining for the indigenous practitioners. This was the dominant view of the British doctors in India; it remains common, though many Indian doctors express guarded sympathy and support for the relevance of indigenous medicine. The second view is the agnostic anthropological, best expressed in Leslie's phrase describing Asian medical systems as 'coexisting normative institutions', in which cultural processes of change are not simply unidirectional (with indigenous medicine being affected by cosmopolitan medicine but not vice versa) but multidirectional, with no predictions of necessary future patterns.[2] The third view is the political structuralist one, in which the superiority of Western medicine follows not from its scientific advances but because it is more closely linked to the class interests of the political leadership in the country.[3] I shall explore some of the strengths and weaknesses of these positions by taking a closer look at policies towards indigenous medicine in India, tracing the links between the British period and post-1947 policies, with particular focus on policy proposals made (and to a lesser extent implemented) since 1971.

Two caveats should be entered here. Firstly, there may be no clear relationship between official discussions of indigenous healers and the situation 'on the ground'. In particular the official mind tends to see the systems of indigenous medicine as discrete and discontinuous, whereas Leslie's model of healers occupying positions which shade into one another seems more plausible.[4] Secondly, there is a great deal of regional variation, not only pre-1947 when the Native States could follow policies radically different from those of British India, but also since Independence, when health policies have been constitutionally the sphere of the States.

The British Period

It is customary to see 1835 as a major turning point in British attitudes to Indian culture. This was the year of Macauley's *Minute* on educational policy, where he argued that European culture should provide the curriculum of schools and colleges. This strengthened the opposition to schemes which attempted a mixing of European and Indian cultures, or were designed to restore Indian culture to its presumed glory. In medical education it meant that the Calcutta 'Native Medical Institution' founded in 1822, would no longer teach aspects of *Ayurveda* (the Hindu medical scriptures, especially those of *Susruta* and *Caraka*) nor of *Unani* (the medical doctrines derived from Greek medicine and more closely linked to Muslim culture). While this move had obvious significance, it did not mean a total ban on such teaching, nor on co-operative relationships between the British Raj and indigenous practitioners as a class. As Hume has demonstrated, for example, in Punjab the Provincial Government employed

hakims (*Unani* practitioners) in the 1860s and 1870s, usually as vaccinators and health extension workers, and the University of the Punjab offered courses in *Ayurveda* and *Unani* medicine until 1907.[5]

One reason for the tolerance displayed by the State is that its own services, and practitioners trained in its medical schools and colleges, had a minimal impact before the end of the nineteenth century. The first four medical colleges (Bombay, Madras and Lahore following Calcutta by the 1850's) produced too few graduates to make much impact on the setting of practice for most indigenous healers, and were mostly employed in the growing State bureaucracy — in the army, the jails, the railways and so on.[6] The 1872 Census of Bengal, for example, enumerated only 3769 physicians, surgeons and doctors, but over 23,700 'Gobaidyas' and 'Kabirajes' (*vaids*, or *Ayurvedic* practitioners) and over 400 hakeems.[7] Prior to the establishment of the Indian Sanitary Commission in the 1860s there was no commitment by the State to provide health care services for its citizens, and there was a slow extension of that commitment beyond plague control and the provision of dispensaries. There was an awareness of the strength of the indigenous groups: plans to introduce medical registration in the 1880s were dropped because the Western doctors were too weak to defeat the expected hostility from the *vaids* and the *hakims*.[8]

A change to greater hostility can be dated from about the end of the century. By this time the cream of the Western doctors in India — the Indian Medical Service, (recruited in Britain though 5% Indian by 1913) was more conscious of its claims to a scientific legitimation: the number of Indian medical graduates and licence-holders was substantial, and they were offering a real challenge to the primacy of indigenous healers in the major towns; and there was the growth of a new middle class which provided new financial opportunities for both groups.[9] The early twentieth century saw considerable political conflict as the rising bourgeois nationalist movement embraced the cause of Indian cultural renaissance as well as the idea of science. The Indian National Congress included leading indigenous practitioners in its ranks as well as modernisers like Nehru. Even within the Imperial Government there were those willing to lend their prestige to new private medical schools, some of which combined indigenous and Western techniques in 'integrated' courses. The general argument used was that it was necessary to improve the training of indigenous practitioners because "for many years to come they will constitute the medical attendants of by far the largest portion of the Indian community".[10]

As Indians gained positions in Ministries after 1919 they were expected to implement policies based on this kind of view, but their scope was limited by severe financial restrictions and their impact was further reduced by pressures from the Indian Medical Services, whose members provided the senior medical civil servants. The new Legislative Councils supported the 'Indian' systems of medicine on both patriotic and economy grounds, but Ministers in several Provinces (e.g. Punjab and Bombay) resisted this and used their limited funds to attempt to bring 'modern scientific medicine and surgery within reasonable reach of all', spending only small sums on research into the indigenous systems and for improved training.[11] As a result, relatively few indigenous medical colleges were given State patronage; the schemes of medical registration excluded those who had not received Western medical training; and the Government of India restricted its activities to an investigation into the pharmacopeia of indigenous drugs.

With the rise of medical registration for the cosmopolitan doctors after 1912, the pressures on indigenous medicine increased. Doctors who offended the imported British ethical codes and collaborated with indigenous practitioners, either in their new colleges or in daily practice, were threatened with deregistration. The wedge between cosmopolitan and indigenous medicine was driven deeper by the disputes over the recognition by the General Medical Council in London of Indian medical degrees, which occupied much of Indian medical politics in the Inter-war period.[12] When the Indian Medical Association was established the early leaders, also prominent in nationalist politics, called for the admission of indigenous practitioners (if they were 'sincere'). By the mid-1930s, when these leaders were being incorporated into the new Indian Medical Council and other positions of influence, they had already drawn back from these positions because such policies might lead to a loss of their international recognition. Indigenous practitioners were first registered in Bombay in 1938, but they were on a separate register from that of the cosmopolitan doctors. They were accepted on the basis of experience or apprenticeship, and only after a 4 year delay was qualification to become the only means of registration. The Bombay Government was well ahead of other Governments, and even here an amendment in 1949 weakened their

legislation and admitted new practitioners on the basis of experience. Nevertheless, the Bombay Act was held up as the model for legislation after 1974.

The inter-war period thus showed gains and losses for indigenous practitioners. On the one hand, there was the establishment of colleges, rather than the less respectable *guru chela* form of apprenticeship which had previously been the sole training method. Several of these colleges were well-funded, especially in Delhi, Madras and the Princely States of Mysore and Hyderabad, for example. The indigenous practitioners also had the support of the reports of special Goverment committees set up to consider policy towards them.[14] On the other hand, their subordinate position relative to cosmopolitan medicine was reinforced by registration patterns, and previous stategies of raising status (e.g. by procuring a scientific facade through joint teaching and practice with cosmopolitan doctors) had received a severe blow. The weakness of the indigenous practitioners was partly a result of their own internal divisions. Not only were there the two main groups separated by linguistic, theoretical and religious differences, but there was also the newer group of homoeopaths, established particularly strongly in Calcutta and Bengal. In addition, each group had a variety of career patterns, usually locally specific, with little agreement about diagnosis or techniques. Often a noted local teacher would prepare his own commentary on the traditional texts, and a school which grew up around one teacher would deride and vilify that around another.[15] These divisions particularly affected elite practitioners, whereas the average healer might be very different—but evidence about them before the 1960s is slight and highly unreliable. Finally, there was the growing ideological split between those who wanted *integrated* teaching of cosmopolitan science and indigenous therapeutics, and those who considered the *pure* indigenous training sufficiently scientific. This divide dominates the post Independence debates.[16]

Different patterns affected female healers—whose history still has to be told. The presumption is that all indigenous healers were male and this is certainly implied by the medical texts and most offical comments. However, many female healers were recorded in the early Censuses, (see Table 1) and some modern fieldwork reports refer to female healers.[17] To be sure, few of these would have had access to the "high culture" learning of the elite male practitioners, but that was true of many of the male practitioners too. The main reason why female healers were invisible to male enquiries was probably that their clientele was almost entirely female. The only group who do appear in the historical discussions are the traditional birth attendants (*dais*), who are recorded separately in the nineteenth century Censuses, and in several early discussions of caste, midwifery is described as the hereditary occupation of the women of particular untouchable castes.[18]

Apart from sporadic training by missionaries in the middle of the nineteenth century, the first serious attempts to train indigenous midwives came in 1902 when money raised in Queen Victoria's memory was put into a fund for this purpose.[13] A sum of Rs 40,000 was available each year, and training followed a scheme first developed in Amritsar in which the *dai* was paid a fee for attending the classes and was expected to attend regularly, to report cases, and to call in the teacher when she had difficult deliveries. Simple examinations were held, and the successful completion of a course

could lead to a diploma and to registration. There are no complete figures for the numbers being trained in any year, but it is clear that a limit was set by the shortage of female doctors or of public health nurses (lady health visitors) to carry out the training. These schemes were based on the following assumptions; that institutional deliveries were very unpopular amongst Indian women (they remain so today); that midwifery was a hereditery occupation amongst certain low castes (the situation is almost certainly more complex than this); and that the *dai* was expected to deal with the menial, polluting, aspects of the delivery. Several features made it acceptable for the State to become involved in *dai* training, in particular, there was no band of Western personnel whose interests were threatened by such training. The *dais* themselves were so poor and of such low status that they could be persuaded into training schemes with relatively little difficulty; and few people thought that the *dai* had any skills worthy of being retained. In all these ways the male healers were different, and this largely accounts for the different policies pursued with respect to them.

Policy After 1947

One of the most obvious ways in which the Congress Governments after 1947 followed the precedents established by the British Raj is in the sphere of health policies. The new Government of India had two sets of proposals to deal with the health problems of the new India : those provided by the National Planning Committee, established by Congress itself in 1938; and those of the Bhore Committee, established in 1943 by the British to plan for reconstruction after the War was over. There was considerable agreement— for example in the proposal that the health service should be free at the point of contact for patients— but where they differed, the post-war Governments followed Bhore rather than the NPC. This was particularly true with respect to the training of part time village level health workers — a corner-stone of the NPC proposals but toally ignored by Bhore. On relationships with the indigenous healers both reports were ambivalent, but Bhore was more hostile. The NPC resolved that

> An attempt should be made to absorb the practitioners of the Ayurveda and Unani systems of medicine into the State health organisation by giving them further scientific training where necessary. Medical training in every field should be based on scientific method.[20]

By contrast the Bhore Report pointed out that the indigenous systems had nothing to say about public health, preventive medicine, obstetrics or advanced surgery, and described the systems as archaic and out-side the onward march of world science. Bhore's policies involved

> a country-wide extension of a system of medicine which, in our view, must be regarded as neither Eastern nor Western but as a corpus of scientific knowledge and practice belonging to the whole world and to which every country has made its contribution. [21]

Proponents of the indigenous systems were able to exploit the ambiguities of these proposals by claiming that science was not the preserve of the cosmopolitan doctors since *Ayurveda* was already scientific; and that only racial bias and a lack of objectivity prevented cosmopolitan medicine from learning from the Indian systems. [22]

The debate over these issues became heated over the first 10 years of Independent India. The 1946 Health Ministers' conference endorsed the Bhore proposals, and ignored the NPC proposals, with the sole exception of its resolution on indigenous practitioners. This was elaborated to include expenditures on

(a) research into the indigenous systems;

(b) the establishment of new colleges and schools;

(c) the establishment of post-graduate course in Indian medicine for graduates in Western medicine;

(d) the absorption of *vaids* and *hakims* after scientific training where necessary, as doctors, health workers etc.;

(e) the inclusion of departments and practitioners of Indian medicine on official boards and councils. [23]

In the face of this strong political pressure, the Government of India followed British precedents and established a committee, under a cosmopolitan doctor (Chopra); most State Governments were similarly slow to act.

By 1947, then it is possible to discern three main organised groups contesting the medical domain in India, the cosmopolitian doctors with a stranglehold on the medical bureaucracy, the 'pure' indigenous practitioners; and the 'integrated' practitioners. A fourth, less organised group campaigned, at least in the 1970s, for the freedom

of unqualified and unregistered practitioners to practice as cosmopolitan doctors. (This group probably best represented the interests of the majority of practitioners in India at the time.) The three main groups have all failed to achieve their own preferred solutions, and most of the issues have recurred again and again in the main policy-making arenas. There are four main topics on which battles have been fought: (1) whether to incorporate indigenous practitioners in the State medical service, or whether to train a separate cadre of community health workers; (2) how to register existing practitioners and those graduating from the indigenous colleges, and how to prevent unregistered practice; (3) whether indigenous colleges should include Western scientific training and an introduction to cosmopolitan therapeutics; (4) whether access to 'allopathic' medicines should be restricted to those registered on the 'Western' medical registers. There were subsidiary issues— for example whether State funds should be used to support training in the indigenous systems or indigenous hospitals— which were agreed in the early period: in fact something under 5% of the Plan health expenditures have been allocated to the indigenous systems of medicine, though these allocations have been consistently underspent.[24] I shall deal with the four more important issues in turn.

1. The Incorporation of Indigenous Practitioners: The cosmopolitan doctors were opposed to any such involvement. In the immediate post-Independence debates they had the support of Nehru and his Health Minister (Rajkumari Amrit Kaur) in arguing with Bhore that all practitioners should have the basic MBBS qualification; if they then chose to practice other forms of medicine that would be up to them—as is the case in the UK. In general it was argued that it was impossible to *integrate* the various systems without causing chaos. However, this was the solution which Chopra proposed: his report recommended that all students should be taught the elements of all systems (like the Chinese solution, at least during the 1970s).[25] Once again the international standing of Indian doctors was used as a powerful argument for rejecting such a move; and the variety of skills and backgrounds of the indigenous practitioners was seen as a reason why no more than perhaps 2% of them could be used in the national health services. While the Government of India thus expressed its hostility, the States were free to act on their own, since health was constitutionally their affair, subject to certain ill-defined constraints with respect to standards of medical education, and health Ministers made their autonomy clear in 1954.[26]

In addition, it was clear that the training of auxiliary medical personnel was regarded as a perferable alternative means of extending rural medical care. A scheme proposed in 1952 was discussed in the 1954 Central Council of Health and in general, those supporting the health auxiliaries were those opposed to the involvement of the indigenous practitioners.[27] However, this proposal was refined and reduced over the next few years, until it was dropped completely.

The early 1970s saw a resurgence of discussions concerning the inclusion of indigenous practitioners. This followed the *'Gharibi Hatao'* election success of Indira Gandhi in 1971. In 1972 the Minister of Health announced a scheme to enlist registered medical practitioners in *Ayurveda, Unani, Siddha* and homoeopathy after a short period of training (4 months), to provide them with a kit containing medicines for common ailments, and thus "to provide medical services to the entire rural area within as short a time as possible, say about three to four years".[28] Apparently this scheme received the strong backing of the Prime Minister, and sanction by the Task Force of the Planning Commission, but when the Health Minister was replaced after nine months, little more was heard about it. However, in retrospect, it can be seen as forerunner of schemes proposed in 1975 by the Srivastav Committee, and in the plans currently being implemented, which are loosely based on the Janata Government proposals made in 1977. The Janata manifesto called for the organisation of "a cadre of medical, paramedical community health workers (CHW) among whom the trained practitioners of indigenous systems of medicine will be a part".[29] In practice, it was decided that the community should choose who was to be the new CHW and they were merely to be advised that the use of an existing indigenous practitioner would be wise. In fact the choice of the CHW has been a highly political decision, heavily influenced by the doctors who were to do the training, and it seems that relatively few CHWs are, in fact indigenous practitioners, whether trained, registered or not. Once again, the offer being made to the indigenous practitioner (fulltime or part-time) was not very attractive, since he would be recruited at the bottom of the medical hierarchy. However, the training schemes included the possibility that the CHW be trained or equipped in indigenous techniques

and therapeutics, and some States recruited indigenous graduates to do the training.

There was no suggestion that the CHW should be a trained *dai*, which is not surprising, given the low estimation of these women. Nor were women with other backgrounds chosen in spite of the experiences of various voluntary schemes which suggested that women were more reliable, acceptable and suitable for this work. Instead, a new *dai* training scheme was introduced, which was essentially just a return to the earlier schemes which had been allowed to lapse in the 1950s. Like the CHWs, they were to be trained at the rate of 1 per 1000 population, and there may have been a feeling that this was the women's proper place. Unlike the CHWs, however, the trained *dais* were not to be given a regular honorarium but only compensated if they referred women to antenatal registration. So far no evalutation of the *dai* training has appeared, though one is planned for 1981.

The impact of the latest schemes is thus twofold. On the one hand, it has meant the inclusion of more indigenous practitioners into State employment: on the other hand, it has created a new band of practitioners who see themselves as potential doctors. Voluntary schemes have also been unwilling to involve the local indigenous healers except in a peripheral way. Once again, the stated reasons have been that the indigenous healers are not relevant in the services which are regarded as high priorities — maternal and child health, or community health services, and there is undoubtedly some strength in this argument.

2. What to do about registering or banning unqualified practitioners: The years following Independence also saw debates about the proper course of action to follow with respect to unqualified practitioners, with moves to outlaw their practice being seriously considered in 1955 and 1959. The discussions in 1955 were inconclusive: another committee was established (the Dave committee) and its report in 1958 (recommending the continuance of integrated courses and the establishment of country-wide registration schemes) was left for States to decide whether to implement. [30]

The 1956 Act which re-established the Indian Medical Council (now called the Medical Council of India) prohibited unregistered medical practice, but the Government of India advised State Governments not to implement that clause. In 1972, after a whole series of discussions in the Central Council of Health, States were advised to follow Kerala's proposal to amend their legislation so that those practising 'modern medicine' for at least 10 years would be registered on a separate list and allowed to continue (but be barred from prescribing dangerous drugs, doing surgery, obsterics or radiotherapy). No further unqualified practitioners would then be allowed to practise. The Indian Medical Association called this a "quacks' charter", and managed to prevent any move on this front — but they could not prevent unqualified and unregistered practitioners from continuing to provide 'modern' medical services.[31]

The 1950s and 1960s saw the slow but steady extension of registration schemes designed to register those currently practising indigenous medicine, but to forbid any new practitioners who had not gained registrable qualifications. As with the model for this legislation, the 1938 Bombay Act, there was considerable pressure against the enforcement of the penal clauses and moves to pass later amendments to include a new set of unqualified practitioners.[32] Even after the 1970 Central Government Act establishing a central policy on standardising the registration of indigenous practitioners, some States were still registering on the basis of experience only, while others insisted on the acquisition of a registrable qualification.[33] By 1977 there were 93 colleges providing *Ayurvedic* education, with a total intake capacity of over 3600 per year; 14 *Unani* colleges with an intake capacity of 485 per year; and one *Siddha* college with 50 places a year [34] However, the total registered as practitioners on the basis of institutional qualifications was much greater than this suggests. It would appear that registration boards take a relatively lenient view of claims to qualifications, or that there is massive double registration (see Table 2).

Table 2.

Registered practitioners in Indian systems of medicine and homoeopathy. 1977

	Institutionally qualifed	Not institutionally qualified	Enlisted
Ayurveda	117765	105344	—
Unani	10262	20138	—
Siddha	1559	16569	—
Homoeopathy	19.871	74166	51397
Total	149457	216217	51397

3. Whether indigenous training should be 'pure' or 'integrated' : Immediately after Independence the supporters of 'integrated' medicine were successful in several parts of the country in establishing colleges and ensuring that the qualifications of their graduates were registrable. However, the counter-attack came fairly quickly. At the 1954 meeting of the Central Council of Health, representatives of most of the North Indian States (including Bihar and UP, the largest) supported the move by the Bombay Government to introduce 'pure' training in Indian medicine. Again the supporters pointed to the 'popularity' of the indigenous practitioners; the tendency in the integrated courses to spend too much time on Western medicine; the incompatibility of the indigenous and the cosmopolitan systems; and the availability of indigenous graduates for rural practice. The opposition argued that science was universal; that it was a crime allow the 'unscientific' to practise in rural areas simply because they were cheap: that there was an absence of senior *vaids* or *hakims* to take teaching positions; and that indigenous practitioners actually used Western drugs and treatments. [35]

These disputes have largely been won by the supporters of the 'pure' school, and by 1975 there was increasing concern expressed by and about the estimated 50,000 integrated practitioners, whose anomalous position with respect to registration and to drugs legislation left them particularly exposed.[36] However, to a considerable extent this was a Pyrrhic victory; most graduates appear to perceive their training as second-rate and it is widely argued that they actually practise using cosmopolitan drugs. In other words, the attempt to reach parity of status has not yet been successful.

4. How to control the use of 'allopathic' drugs : Finally, in spite of an agreement in 1958 that only those with Western medical qualifications would be permitted to prescribe the drugs listed in the 1945 Drugs Rules, this too was not implemented. This was complemented by an apparent unwillingness to make serious attempts to enforce general controls on pharmacists and pharmaceutical companies, so that there is little or no effective control over access to any drugs in India. This alone tends to nullify almost all the other decisions with respect to indigenous healers. As Neumann and others have shown most 'unofficial' healers, whether registered as *vaids* or not, tend to prescribe largely from the cosmopolitan pharmacopeia.[37] With relatively free access to these drugs, there are continually new practitioners becoming established on the basis of experience. Indian political culture seems to accept as legitimate the claim that they have rights to a livelihood in this way. One of their strongest arugments is that they provide services where cosmopolitan doctors are unwilling to go — in the rural areas. Nevertheless, many of them actually practise in urban areas, but through their links with politicians they seem to be able to prevent punitive action against themselves and to be able to make powerful political cases for the amendment of hostile legislation.[38]

Conclusion

One of the difficulties of making clear assessments of the nature and effect of Government policy with respect to indigenous healers is that there is no clear line being followed. On the one hand, it is clear that indigenous medicine is essentially marginalised, with many of its practitioners part-time, dealing with a limited range of ailments, drawing heavily on the cosmopolitan pharmacopeia and perceiving cosmopolitan medicine as superior. Government policy, particularly in terms of employment and expenditure, reinforces this trend. On the other hand, there is a trend towards greater respectability, with the extension of registration schemes, the recognition of indigenous contributions by the international agencies and in CHW training, and some steady expansion of employment. The failure of attempts to suppress or control unqualified practitioners, and the loop-holes in registration schemes, mean that the cosmopolitan and qualified indigenous practitioners alike are theatened by 'unfair' competition which is outside their control, so that the formal commitment to the modernisation of medical care in India is very different from the reality.

There seem to be a few threads which can be drawn out of this, however. Firstly it is clear that indigenous practitioners of all kinds do provide an alternative which the Government has to come to terms with whenever its legitimacy is weakened. The greatest advances have come in the period when the new Republic was being established; when Congress was reasserting its supremacy after its losses in the late 1960s; and during the Janata regimes since 1977. Secondly, it is clear that the alternative solution to the problem of providing a cheap extension of Government health services to rural areas — the employment of para-medical personnel or community health workers — has been preferred. This has been premissed on the idea that they will be more controllable, and less likely to claim the status of 'doctor'—when of course

this is the major complaint of the cosmopolitan doctors and the major aim of many CHWs.

In terms of the arguments with which I opened this paper it is clear that all of them have their weaknesses. Indigenous practitioners are not dying out, they are infiltrating Government and retaining considerable popular appeal, even in urban areas. On the other hand, their impact on cosmopolitan medicine is a great deal less than the influences the other way, and the indigenous systems remain subordinate. Yet to argue that cosmopolitan medicine alone meets the needs of the ruling class is also inadequate, since the very political support which the practitioners can generate by virtue of their positions means that politicians woo them assiduously, even if they no longer have a coherent ideological position which commands much support. It is much easier to see how women healers are being marginalised and excluded from positions of influence than to draw clear pictures of the nature of the changes amonst the men.

SYSTEMS OF MEDICINE: ROLE AND RELEVANCE

sujit k das and smarajit jana

While traditional medical systems passed their peak centuries ago, modern medicine has not entirely replaced them. The issue of traditional v|s modern medicine, the authors argue, is essentially an ideological one, governed by political interests; this is illustrated by the variance in the official, semi-official, and progressive views on the subject. Even the Chinese experience, the authors say, demonstrates this. Systems of medicine, as such, in their opinion, are irrelevant in the context of a people-oriented and egalitarian health system, in which they will comprise merely a set of therapeutics. Thus the entire debate on the role of traditional medicine is academic.

The historical development of health care in the western societies has been analysed and explained in various ways. Those analyses bear relevance to the Indian situation to the extent that western medicine (allopathy) had been introduced and developed by the colonial power and after independence, it developed rapidly with State patronage. Traditional systems, however, passed their peak of development long ago, but existed and persisted in Indian society.

Among the traditional systems, the oldest one, Ayurveda, reached a very high level of development. Ayurveda is the fore-runner of Indian scientific development and the father of materialist philosophy. Ayurveda is a comprehensive body of knowledge in medical science having well developed or rather too highly developed theoretical foundation based on empirical data, scientific methodology of observation, experimentation and analysis, and disciplined norms of practice. Ayurveda asserts that all things living and non-living are products of natural matters; disease is the result of material change in the body due to interaction with natural matters; and therefore could be corrected to an extent with the help of natural matters (drugs). Charaka-Samhita declares, "There is nothing in nature without relevance to medicine". There is nothing supernatural about natural and human events. In ancient society, the dominant ideology of the all-powerful ruling class was totally and oppressively anti-materialist. Materialist heretics actually had no right to live. That is why, all extant source books of Ayurveda are found to be camouflaged with enormous amount of metaphysical and religious garbage with a view to project an appearance of conforming to the dominant ideology. (Chattopadhyay, 1977). But what now exists and is practised as ayurveda or sidhha is not the ancient dynamic science of ayurveda but a decadent form which absorbed the alien metaphysical interpolations as truth and degenerated. The other major existing system Unani, the legacy of Greco-Arab medicine, is no different.

The scientific basis of modern medicine developed later. Starting from the 19th century, it developed on the shoulders of physical and biological sciences in the 20th century — achieving a tremendous speed after the 2nd World War. It has been argued that British colonialism brought along with it destruction and decay of the indigenous systems of medicine (Banerji). But there is little data available to substantiate this view. Others claim that modern medicine did not make much impact except with limited urban population; the largest section of the population still depend on indigenous systems, which is dealing more or less satisfactorily with many of the health problems of the local people. (Bannerman et al, 1983)

Alhough the state health care service has been built on the principles of modern medicine the indigenous systems including homoeopathy have been receiving state patronage in the later period. Budgetary allocation on the development of indigenous systems and homoeopathy has been increasing since the fourth plan period and the number of their practitioners as well as infrastructure have now reached impressive proportions.

	Total No. of Regd. practitioners	Admission capacity	Hospital Beds	Dispensaries
Ayurveda	2,32,247	3,306	9,783	12,027
Unani	22,756	535	627	986
Sidhha	18.190	75	—	426
Homeopathy	1,09,493	7,513	2,249	1,782
Modern Med.	2,68,712	10,934	4,86,805	17,455

Source : Health Statistics of India; CBHI., Ministry of Health & Family Welfare, GOI, 1983. Figures are incomplete due to lack of information from a few centres.

To this figure if we add the number of various paramedical personnel e.g. Pharmacists, Nurses of different categories, MPHW, LHV, Health Assistants and Supervisors, CHG, midwives, one may arrive at the conclusion that India does not need any more doctors at all for a comprehensive health care delivery system (ICSSR-ICMR, 1981). Still the official view, which is inherently wary to admit failure, is that the state health services have been unable to meet the actual health needs and priorities of the people, have been hospital-based and cure-oriented neglecting the preventive, promotive, public health and rehabilitative aspects of health care, and benefiting only the upper crusts of the urban population (GOI, 1982).

The Question of Different Systems

The official view :

The rising aspiration of the masses and increasing demands of medicare from the disease-ridden people, particularly incensed by the glaring difference in the standard of medicare between the haves and have nots, have so far been chiefly instrumental for increasing allocation in the state health sector. People have also become aware of the discriminatory availability of the state service. The government, therefore, has to admit the existing reality which is self-condemnatory and with the view to find a way out, advocated promotion of indigenous and homoeopathic systems of medicine. To provide ideological cover, a large number of virtues of those systems have been discovered and invoked, e.g. rich heritage, glorious achievements and cultural compatibility (GOI, 1982). The government realises that if the grievance of the larger section is contained by providing them with low-cost non-allopathic systems, the absolutely necessary but costly provision of modern medicine for the affluent urban section can be safeguarded. But, the life-saving contributions of modern medicine cannot be entirely withdrawn from the people. Hence, the question of integration. It has been recommended that the practitioners of the non-allopathic medicine must have a 'basic knowledge of human anatomy, physiology and other necessary medical knowledge'; research should be carried out with modern equipment and diagnostic methodology, so that it becomes acceptable to the modern scientific world; modern technology be introduced for the manufacture of traditional medicine and specific standards be adopted to ensure quality of raw materials and manufactured products. For integration of the indigenous and modern systems, the services of non-allopathic practitioners should be integrated, at the appropriate levels, within specified areas of responsibility and functioning, in the overall health care delivery system (GOI, 1981 and 1982).

The leaders miss the point that if the above measures are implemented, nothing remains of tradition and the very indigenous character is wiped out. They also forget that the non-allopathic systems have little to contribute towards preventive, promotive, public health and rehabilitative aspects of health care. But then, their concern is not so much for traditional systems as for availability of some acceptable form of medicare for the uncovered population.

The semi-official view :

The study group of ICSSR—ICMR recommends that there should be a national system of medicine with 'synthesis', and not 'integration' of different systems; practitioners of indigenous systems be utilised in the national system; each system be allowed to retain its own identity and grow according to its own genius; in medicare institutions patients be offered choice of systems; in course of time all training institutions of medical and health personnel will teach one and same system of medicare with individual systems being offered as specialisation courses at the post-graduate level; and in the same breath, 'in course of time medical graduates from any medical college would be able to provide such multi-system care' (ICSSR—ICMR, 1981). Earlier an official committee also recommended a national system of medicine and health services, in keeping with our life systems, needs and aspirations. (GOI, 1975).

It is clear that these recommendations are s full of self-contradictions and wishful thinking that these cannot be taken as anything but hasty remarks. But one point is obvious. The observers are anxious that somehow the non-allopathic systems be supported and given a place, whatever that may be, in health care service.

The WHO, has since come out as another champion of traditional systems. Facing the reality of shortage of personnel and provisions of MM, and the existence of a large number of practitioners of other systems, the WHO calls for integration at appropriate levels but also suggests selective scientific training for personnel and scientific biomedical research into their therapeutic materials.

The above views, while talking about cultural compatibility, commercialisation and high cost of modern medicine have introduced another ideological

pointthat health is essentially an individual responsibility (GOI, 1975), and that community participation is the process by which individuals and families assume responsibility for their own health and welfare and for those of the community (WHO-UNICEF, 1978).

The non-official progressive view :

Essentially the progressive views on the question of non-allopathic systems evolve from their critiques of modern medicine. There is no such thing as medicine in general; medicine is always articulated in a given social formation and the mode of production of that social formation gives rise to its corresponding medicine; thus we can only speak of feudal medicine, capitalist medicine, or communist medicine; thus, modern medicine, is capitalist medicine. It has a dual function : (a) dominance and control, exercised to maintain the exploitative relations of production, and (b) useful and needed function, which is necessary in any society, to contribute to the care and cure of the working population. These two functions are not separate but, rather, the control function is exerted through the useful function (Navarro, 1983) Modern medicine is mechanistic and reductionist giving rise to professionalism and mystification, establishing the domination of a class of elite health professionals who propagate, reinforce and maintain bourgeois ideology (Waitzkin, 1984). Perhaps the most profound, impact-making critique is that of Ivan Illich. His analysis of clinical, social and structural iatrogenesis, leading to growing medicalisation of life exposes the negative effects of modern medicine in a telling manner. (Illich, 1977). Modern medicine, based on the paradigm of clinical medicine, even at its most progressive limits persists as an individualistic, class-biased and ideological mode of diagnosing, treating and preventing illness, and is necessarily inadequate as it ignores the socio-political and economic determinants (Turshen, 1977).

To obviate the negative effects of modern medicine, a number of prescriptions have been offered, the promotion of traditional systems of medicine being one of them. The Chopra Commitee (1948) recommended the use of indigenous systems at the lower level and synthesised medicine at the higher levels of medicare, and it has been lamented that had these recommendations been implemented at that time, it would have resulted in a drastically different system of medicine. (Jesani & Prakash, 1984). Though the present official view, is veering round to these recommedations, there appears to be little prospect of the development of a drastically different system of medicine. While emphasising the alien identity of modern medicine and cultural compatibility of indigenous medic ne, and recommending maximum use of self-care procedures and various home remedial measures, services of traditional healers of various systems, and community-selected primary health workers, Banerji conceds a central scientific core in modern medicine and seeks its separation for correct application in Indian care system (Banerji 1982). Others, while deprecating unnecessary polemics between different systems, call for 'a coherent synthesis of the valid elements of the different systems of medicine into a modern scientific health science', and argue that simplified scientific analysis of drugs and remedies of different systems and their propagation among the people will result in self-reliance of both the people and drug availability. "Ayurveda can continue to provide valuable ideas for reserach in basic and applied biomedical research. But this would be possible when Ayurveda undergoes a basic transformation. Ayurveda has to become Ayur-Vigyan (Science)" (Vaidya). Another intensely vigorous view is the Report of the Committee on the Indigenoue Systems of Medicine. Even after a long period of neglect due to absence of State patronage and well over a century after the introduction of western medicine which became the sole recipient of state help, the indigenous systems of medicine were not only serving the need of over 90% of our people, but doing so much more effectively and economically than western medicine" (Government of Madras, 1923). This view denounces the attempt of synthesis by placing the indigenous remedies under scrutiny of modern science and, asserting that the present location of different systems is due to the political process, urges clear identification of a system of medicine that can meet the needs of our people (PPST, 1984). In respect of tribal societies, it is claimed that tribal medicine which is actually based on ancient ayurveda, is competent enough to meet the local needs and for the protection of cultural identity and with the objective of self-reliance, entry of modern medicine should be barred (Shankar, 1985).

The Chinese connexion

All these views almost uniformly draw inspiration from the Chinese model which is hence, discussed separately. The Chinese policy, a few years after revolution, of integrating the traditional medicine and practitioners into the mainstream of medical education and health care service, received worldwide publicity and almost universal

appreciation. It has since been hailed as a success. Attempts have, therefore, been made to introduce this policy in several Third World countries with disastrous failures which have later been explained as due to difference in socio-political-economic structure. But the actual Chinese model has seldom been painted clearly and truthfully.

The basic aim of the Chinese health care service in the fifties was to maintain, develop and raise *production* both in rural and urban context i e. agriculture and industry. It has been repeatedly stressed in the health policy of the government and the party that the principal aim of health work is to ensure industrial and agricultural production. This fact may embarass the strident critics of capitalist medicine and health care which is accused of pursuing the very same aim. Agriculture being the mainstay of the economy, organised rural health care is practically non-existent, health personnel and infrastructure being miserably inadequate, the earlier Mao Tse Tung thought has been invoked, ".... to rely on modern doctors is no solution. Of course modern doctors have advantages over the doctors of the old type, but if they do not concern themselves with the sufferings of the people, do not train doctors for the people, do not unite with the thousand and more doctors and veterinarians of the old type in the Border Region and do not help them to make progress, then they will actually be helping the witch doctors and showing indifference to the high human and animal mortality rates". Mao's reference to withchraft is very real. Joshua Horn's own experience told us that the services of the traditional practitioners was available only to the rural elite, because they were highly professionalized and expensive and the herbal medicines were also very costly. The overwhelming majority of the poor villagers had actually to depend on the village quacks and witch doctors in pre-revolutionary China (Horn, 1971)

Integration of Chinese medicine with modern medicine is only a part of a whole comprehensive health care service. This policy is based on the principles of modern medical science and operated through indigenously available technology, and infrastructure. 'Mass line' in preventive work and environmental protection, emphasis to maintain production, integration of traditional doctors for man-power mobilisation in medicare, comprehensive coverage of population, rapid production of health personnel, and political dominance in health administration — are the basic elements. Regarding integration, the policy adopted at the First National Health Conference (1950) was based on the attitude that in view of the shortage of doctors and medicine, Chinese traditional medicine should be utilized (because it was there and readily available rather than because of any inherent value it had). In the policy of 'unity and reform' the stress was on reform of the traditional system by the western. When this attitude failed to bring the desired results, the political command intervened and the campaign for superiority of Chinese culture and glorious tradition of Chinese medicine was launched which enhanced the social status of the traditional practitioner and resulted in more widespread use of herbal remedies. "Even when herbal remedies were not very effective, they were of considerable importance as they still provided the peasant with some support, whereas if it had been decided that only modern drugs should be used, he would have none at all as expenses would have placed any drug therapy out of reach. The use of herbs for the purpose of psychological support — though not explicitly admitted in the Chinese press — is not much different from the wide variety of placebos offered to patients daily in industrialised countries". (Wilenski 1979).

From the beginning of the sixties, the enthusiasm towards traditional systems ebbed, and professionalism and elitism again started gaining dominance; even the traditional practitioners were concentrated in the larger country towns and served on the basis of private practice Mao's intervention at this stage on the eve of the cultural revolution reversed this direction. In his famous June 1965 directive Mao said, "Tell the Ministry of Public Health that it only works for 15 per cent of the entire population. ... The Public Health Ministry is not a people's Ministry. It should be called the Urban Public Health Ministry or the Public Health Ministry of the privileged or even the Urban Public Health Ministry of the privileged Medical education must be reformed. .... A vast amount of manpower and materials have been diverted from mass work and are being expended in carrying out research on the high level, complex and difficult diseases, the so-called pinnacles of medicine. As for the frequently occuring illnesses, the widespread sicknesses, the commonly existing diseases, we pay no heed or very slight heed to their prevention or to finding improved methods of treatment. It is not that we should ignore the pinnacles. It is only that we should devote less men and materials in that direction and devote a greater amount of men and materials to solving the urgent problems of the masses. .... We should keep in the cities those doctors who have been out of

school for a year or two and those who are lacking in ability The remainder should be sent to the countryside". (Mao, 1977)

The large numbers of the health professionals since sent to work in the rural areas soon realised that they could not handle the vast burden of rural ill health and also they could not hope to return to urban institutions without an alternative rural health service. Soon emerged the barefoot doctor who is neither a paramedic nor a doctor's auxilliary, but a part-time doctor trained in diagnosing and treating, without assistance, common or recurrent diseases prevailing in the locality. The scheme succeeded for the chief reason that medicare infrastructure had since been organised on the basis of universal coverage right up to super-speciality at the top most level with efficiently functioning referral system. But the recent trend is a shift towards greater professionalisation and medicalisation of the health system, higher education of the barefoot doctors, greater emphasis on higher quality of medical education with the return to seven-year curriculum, and more research centres, modern hospitals, specialists and technologically sophisticated interventions (Rhode, 1983). China now takes pride in letting us know that she, in 1982, has 9,52,000 doctors of modern medicine compared to 2,90,000 of traditional medicine and 2000 senior doctors of modern medicine also trained in traditional medicine While in the year of liberation, there were 10,000 fully trained and 30,000 partially trained doctors of modern medicine and 5,00,000 traditional practitioners. (Wilenski, 1979).

The culture issue :

Concern for Indian culture is the common issue in the agenda of the advocates of the traditional or integrated systems. "Perhaps the simplest and most useful formulation of the concept of culture is to say that it is acquired or learned system of shared and transmittable ways of adjusting to life situations. .... A common characteristic recognized in all treatises on culture is *change*, a capacity to shift, accumulate or loose components, which makes culture far more flexible and variable than are the somatically determined patterns of behaviour" (Simmons & Wolff, 1954). Culture is not a rigid frame, inert model, or static dogma of guidelines governing community or individual conduct. Culture is built up on complex interactions — involving physical, environmental, ideological, political, and predominantly economic. Economic relations i.e. relations of production, exchange and consumption, find expression in cultural and social responses, and changes in the economic relations bring about profound changes in the cultural matrix. Tradition is not culture. Tradition is the vestiges of earlier cultural trends, and ideologically influences the present and future trends. Just because the peasant lives with the bullock cart for generations, he should not be taken as culturally bound to the bullock cart, or demands to remain so Adherence to witchcraft and ideological allegiance to the metaphysical theory of health and disease do have their roots in economic relations and is a reflection of the stage of development of the productive forces and superstructure. While on the one hand, the capitalist onslaught on the tribal ways of life does produce disastrous consequences, on the other, the urge to protect the tribal identity gives rise to irrational obscurantism which is anachronistic to progress and inadequate to meet the need. Such an urge often leads to the proposition that western medicine is not essential for India's particular needs and we are entitled to a separate scientific medicine relevant to our social-cultural-historical context (Bajaj, 1985).

A carefully planned study of health behaviour of rural population of India has revealed "that the response to the major medical care problems was very much in favour of western (allopathic) system of medicine, irrespective of social, economic, occupational and regional considerations. Accessibility of such services (modern medicine) and capacity of the patients to meet the expenses were the two major constraining factors" (Banerji, 1974). In contrast, the observations of studies conducted in 1951-52 in villages of Rajasthan and UP reveal that the villagers largely rejected the western medicine in favour of witchcraft and traditional remedies (Carstairs and Marriot 1955). This profound change has occurred not only due to the remarkable curing and life-saving remedies of modern medicine but also from economic changes in all spheres of rural community life and consequent politico-ideological changes. A study by 13 social scientists in the Toushan commune health clinic of Kuangtung province, China, concludes that incorporation of indigenous medicine into the organised health care service is a rational move on political, ideological, technical, socio-medical and economic grounds but conceds that 70 percent of patients opt for western medicine. Medicine bag of the barefoot doctor carries 80 percent drugs of modern medicine (Lee, 1982). In Shangdon province, China, the number of x ray examinations increased by 80% in the rural areas in 4 years ('76-80'). Of the total 4111 x-ray machines in the province, 3824 are situated in rural and district hospitals (Feugetal 1984). The

assertion of cultural compatibility of traditional medicine in India appears to be a myth. The Government of West Bengal has for some years appointed homoeopathic and ayurvedic practitioners in the rural health centres. In all such Centres they not only remain idle but usually their services are utilised for other purposes. No quantitative study is available on the practice of use of modern drugs and implements by the non-allopathic practitioners. Journal of the IMA (June, 1985) published a letter from one Dr Buch who complained that the existing govt rules precluded him from recruiting 15 Ayurvedic graduates, who he interviewed, for a TB hospital at Keshod, Gujarat, which had been suffering from extreme dearth of doctors, even though all those Ayurvedic doctors were practising MM in the nearby villages. He lamented, "Why we continue to waste our national resources on such education which our youth decline to practise in future?"

The other issues :

Mystification : is more pronounced in the traditional systems which draw sustenance from metaphysical philosophy and fatalistic belief regarding health and disease, isolated from environmental and socio-economic-political determinants. In contrast, the body of knowledge of modern medicine is not only universally accessible but, shorn of its avoidable terminology, this knowledge can be and has been mastered by non-medical personnel. Because of its integral relationship with other physical and biological scientific disciplines, modern medicine has largely been demystified at the higher functional level. The mystification of the practice of modern medicine is not an isolated phenomenon but is prevailing in all other professions including even the legal profession which does not depend on science and technology. This mystification is a feature of market economy and an instrument of exploitation and profit. Demystification at the level of practice can be brought by change in the economic relationship and not by replacing with more mystified traditional systems.

Professionalism : which also is utilised for profit and exploitation is similarly a feature of commodification of medicine and has little to do with systems of medicine. With the gradual dimunition of the commodity character of medicine, China has curbed professionalism to a great extent. On the other hand, in post-revolutionary Cuba, professionalism has been encouraged and strengthened in a State monopoly health system but that did not pose any constraint in the way of establishing an egalitarian health care service. Though professionalism prevails in Cuba to an absurd extent (only doctors are entitled to give injections), still Cuba has made remarkable strides in raising the health status of the people and the health system is free from professional explotiation.

Individualism, Mechanicism, Reductionism, Class bias, Commodification, etc : These are not peculiar to any system but owe their roots to the economic base and the dominant ideology. Rather it can be conceded that modern medicine is least endowed with these vices because it has opened up the possibility of taking a materialistic and holistic view of health and medicine, owing to large expansion of the data-base and knowledge-base of the natural sciences and social sciences; growth of socialisation of production is bound to develop socialisation of medicine. Choice of systems of medicine has little relevance to this change.

On the other hand, a rational view towards all these elements should also be evolved. One who vigorously attempts to expose the bias of capitalist medicine against people's interests, may run the risk of making a fetish of these elements. Individualism, mechanicism, reductionism etc. are not touchstones that turn everything they come into contact with ugly. In all social functions, some practice of mechanicim and a reductionist analysis are inevitable at the micro level. Given the operation of socialist analysis and policy in the health care programme of a socialist society, at the micro-level it is reduced to providing treatment for sick individuals who, having similar socio-economic background, may happen to differ widely among themselves in respect of physical, psychological, behavioural characteristics as well as in the quantity and quality of their responses to medical intervention. Indeed, the situation is necessarily reduced to taking a mechanistic, individualistic and interventionist approach in performing the instant task of attending to a sick indivdual who is not only a number as featured in the policy and programme making at the macro-level, but also a human being possessing a distinct personality and capable to respond to and interact with, employing his own judgement, the medical provisions earmaked for him by the organised society.

The Real Issue

The real issue is to formulate, organise and develop an egalitarian health care service — with preventive, promotive, curative and rehabilitative

aspects. Such an ideal is realisable only in a non-exploitative economy. Doyal and Pennell have shown that in the Capitalist economy, development of medicine and organisation of health care follow the needs, priorities and prerogatives of economic relations. That is why we find changing emphasis on public health, curative medicine, individualistic medicine, population control and so on in different periods. "It is ultimately profit, rather than a concern to improve overall living standards, which is the most important determinant of economic and social decision-making in Capitalist society" (Doyal & Pennel, 1981). Rejecting the anti-technology, anti-industry and anti-modern medicine stance of Ivan Illich, and acknowledging its positive achievements in the health sector, they argue that modern medicine is neither a value-free science nor an altogether evil force, and that its till effects could be overcome in a radically changed socio-economic order. Indeed, the idea of changing the character and organisation of discriminatory and exploitative health care by choosing and introducing a particular system of medicine, itself appears to be a mechanistic, instrumentalist and utopian view. True, it is conceivable that mobilising the large number of traditional practitioners and comparatively cheaper herbal remedies under the State sector following the Chinese model, a large section of uncovered population may be offered some form of medicare. But such a view is hardly relevant in the Indian context on two counts. One — unlike China there is no state-monopoly control over the health system in India and hence it is not feasible. Second — it needs to be assessed first, if India lacks in the necessary number of trained personnel in modern medicine for the operation of Primary Health Care Service of comprehensive coverages Commenting that "the argument in favour of the use of traditiona practitioners does not question why even modern practitioners of private medicine have not been properly integrated into third world health care services", Oscar Gish stresses that the major obstacle is not the limited resources or technological deficiency, but the social system which places a low value on the health care needs of the poor (Gish, 1979).

Why then all these debates about traditional systems ? Since the political independence of the colonies, in the era of neocolonialism the poverty of the third world masses continue to be a headache of the imperialist camp. 'Economic growth' approach was introduced stating that the primary need is rapid increase in GNP which will necessarily trickle downwards to alleviate poverty. After two decades when this strategy failed, lately a new 'basic needs approach' has been advocated. Ibrahim Samater has, in an analysis of the strategy and tactics of the controllers of international economy, shown that this new approach is another attempt to contain the growing unrest among the exploited and deprived population of the third world, and that it is also bound to fail because without any change in the property system, in power relations and in the demand structure, the basic needs e.g. food-cloth-shelter-water-sanitation-health etc. cannot be met. The ruling class needs to uphold and maintain the image of the state as the benevolent arbiter for the masses and the state thereby needs to put priority on relief and medicare. Physical ailment, debility, death are extremely sensitive elements with political consequences. The benevolent image of the state distributing medical relief often atones for its other failings. One may be poor or unemployed but when the state is there to save him from death due to illness, the benevolent image brightens. But this benevolence is difficult to mediate through the provisions of modern medicine. The cost is prohibitive and will necessarily erode the profit margin reducing capital accumulation. The only alternative way appears to be the glorification of the achievements of the traditional systems with a coating of the theory of cultural compatibility. The culture of course, refers to poor people's culture — not of those who can afford to purchase modern medicine. The vigorous promotion of traditional systems by official and semi-official circles is not out of conviction in the efficacy and inefficacy of traditional and modern medicine respectively, but out of pragmatic political considerations with the purpose of co-opting and weakening any challenge to the existing exploitative socio-economic order which actually is the cause of the deprivation of the basic needs e.g. health care. An uncritical support to this strategy by the progressive health activists will be a liberal humanist deviation propelled by subjectivism.

From the foregoing it is evident that choice of a particular system or any integrated systems is of little relevance to the demand of a people-oriented egalitarian health system. The traditional system, at their best, can offer a few remedies in curative practice. A comprehensive health system will have to be based on scientific tenets, but while the underlying theoretical pre-conceptions of scientific will need to be critically re-examined to identify the elements of class-bias and mechanistic paradigm, the operative infrastructure should be explored to resist and eliminate the commercialism, mystification, professionalism of the medical practice. Scientific

medicine is a product of modern science developed in the Capitalist regime. While welcoming and practising modern Science and Technology in all fields of social life and economic development, rejection of modern medicine is not only anachronistic but utopian.

The role of traditional systems therefore appears to be limited to effective (organic and functional) remedies for medicare, employed under the same regulatory mechanism as that of modern drugs. Relevance of the apparently unending debate on the choice of a suitable system of medicine is only academic and sterile in the context of our search for a people-oriented comprehensive health care service.

A SEARCH FOR ALTERNATIVES
Organising Vaidus in Gadchiroli

ravindra r p

Gadchiroli, a predominantly tribal district in Maharashtra is currently witnessing a new experiment in providing appropriate health care. The vaidus, local healers, of the area have come together to revive and even reformulate an ancient system of healing which is fast vanishing in the face of exploitative inappropriate medicare. A report.

Experiments in community health initiated in the seventies have now come to stay. There have been several attempts of evaluating such projects, the latest being by Sumathi Nair (SHR II.2.) With due acknowledgement of the contributions of these projects to community health, their limitations are being increasingly identified. The multiplicity of such models is low due to the requirements of heavy inputs in terms of resources like finance, know-how and skills, drugs, training and referrel facilities and personnel and so on In most cases, the political component of health/life of community s ignored, sidetracked or played down. Most such projects revolve around 'Allopathy" which brings with it its inherent limitations, moreover, although allopathy is the 'least unscientific' method, it remains culturally alien to most people.

It has thus become imperative to search for new alternatives, free from the above constraints. In this article, I wish to describe one such experiment of organising vaidus (traditional health workers) undertaken by the 'Paramparagat Vanaushadhi Vikas Va Samshodhan Kendra' (Centre for Development and Research in Traditional Herbal Medicine) in the Gadchiroli district of Maharashtra. However, neither the author nor activists of the 'Kendra' wish to claim that it is the only alternative. It can, at best, be one of the several alternatives. The form and content of each such attempt could depend upon local conditions and priorities of the experimenting group.

Gadchiroli (formerly a part of Chandrapur) is a predominantly tribal district on the borders of Maharashtra with MP and AP. In the 'fifties' it was a stronghold of socialists when Narayansinh Uike, the first tribal graduate from Vidarbha region of Maharashtra, organised tribals around issues of land distribution, education and atrocities by ruling classes. Recently, some activists of Chhatra Yuva Sangharsha Vahini (the same group which supports the Kendra) have succeeded in organising large numbers of landless labourers and peasants working under the Employment Guarantee Scheme (EGS). Attempts are being made to launch a broad-based 'Nisarg Bachao, Manav Bachao' (save nature, save humankind) agitation to oppose the proposed Inchampoli dam, which is expected to cause largescale deforestation and evacuation of many tribal villages in the nearby districts. Sukhdevbabu Uike, a follower of Narayansinh Uike and an activist associated with EGS and Nisarg Bachao has recently been elected to the Assembly from this area. All four MLAs from this district belong to opposition parties, much due to influence of activists in EGS and Nisarg Bachao.

The same team of Vahini activists has, for the last three years, undertaken the task of organising vaidus, with a view to evolve an alternative system of healthcare service which can be made available to the needy as and when required. It is not just a revival of an ancient system crumbling against the pace of changing times, but an attempt to evolve a dynamic system challenging the monopoly and mystification of established medical system. It would be integral to the cultural mileu of people and within their reach. It would be a system based on experimentation, experience sharing and an urge to serve the people (and not for profiteering). The team is trying to evolve democratic methods to achieve this object without the use of foreign aid or even possibly full-time workers. Judging by the meagre input of time, finance and people, it would be unjust to pass any judgement about this venture. However, their experiences undoubtedly point towards newer sign-posts in community health.

Vaidki in Gadchiroli Today

Vaidus are traditional experts in diagnosis and treatment of diseases; collection, processing, compounding and dispensing of medicines without any economic incentives. For them, this is a noble service, not a profession. They are mainly responsible

for health care of poor people, patients with chronic ailments and in far-flung areas yet inaccessible to modern health services. The transfer of knowlegde is mainly from father to son or to other worthy male member of community. In exceptional cases, where sons are unwilling/unworthy the knowledge is passed on to the daughter-in-law (but not to a daughter as she 'belongs' to a different family). Many vaidus, specially the educated ones, try to enrich knowledge gained from the Guru through experimentation and study of Ayurvedic texts. Vaidus in this area use drugs from plant, mineral and animal origin as well as mantras (chants) for treatment of physical and psychological disorders. They have their specialisation such as asthma, snakebite, veterinary diseases and claim to cure diseases untreated by modern medicine-tetanus, cancer etc. Although it remains to be seen how many of these claims stand scientific scrutiny, there are many instances confirming this skill in diagnosis and treatment. They follow several guidelines laid down in Ayurveda regarding the day, time and season of plant collection, diagnosis of diseases and processing of crude drugs. Some formulations used by vaidus are referred to in Ayurvedic texts.

Current Issues confronting Vaidki

The processes of 'development' and 'modernisation' have disrupted the socio–economic-cultural fabric which sustained and nurtured tribal life and specially their system of medicine and posed grave threats to their very existence. Like its counterparts everywhere, Gadchiroli has witnessed massive butchering of trees, disruption of the intricate eco-balances triggered by profit-hungry commercia interests hand in glove with government officials. An interesting example of 'modernisation' with total disregard to people's real needs is a dairy recently set up after destroying several acres of rich forest. Its premises have been declared as 'prohibited area' for outsiders. Hence vaidus are denied access to the few medicinal plants which have managed to survive in the compound. It's an agony to watch a patient suffer due to non-availability of a drug whose whereabouts are known, but which cannot be procured. The dairy has not in any way helped the tribals. It has only resulted in a complete drought of milk in the villages.

Large strips of forests are burnt by contractors for a better yield of tembhurni leaves (used for making bidies). Moh trees, of great economic, cultural and medicinal significance are burnt down and truckloads of coal sent to cities. The rich, symbiotic flora is being replaced by large scale plantations of monocultures of teak and eucalyptus. Many valuable medicinal herbs have become scarce, some extinct. Ironically, such 'modernisation' has encouraged supersitious practices. Due to the depletion of herbal medicines, many vaidus are resorting to more non-drug 'therapies' like mantras, talismans, animal-sacrifices and so on.

'Development' has brought to tribal towns a new exploiting species — 'doctors' who, posing as demi-gods, promise instant relief and cure-alls through miraculous modern drugs, ushering in a culture of injections and antibiotics. The 'moderno-philia' has lured people to spend their meagre resources on unnecessary (often harmful) drugs and cultivated in them distrust for their traditional system of medicine. (The is not to deny the utility of modern medicine but to protest against its present misuse).

Even then, established medical professionals often feel threatened by the skill and knowledge of vaidus. There was an interesting case of a veternary doctor who extraced large sums from people and was still unsucessful in a number of cases. The cases given up by him were then successfully treated by a young, dynamic vaidu. The people jeered at the doctor, who, in turn, lodged a complaint against the vaidu for practising medicine without registration. However, the village people unitedly stood behind the vaidu and did not allow the police to arrest the vaidu. With growing assertiveness and awareness in vaidus resulting from their organisation, more such attacks from medical establishment are likely to follow.

Vaidus manage to earn their living in difficult summer days by selling crude drugs to traders who take full advantage of the situation. Arjuna bark bought at the rate of 5-10 paise/kg is sold by middlemen to drug companies at the rate of several rupees/kg (that too after considerable adulteration).

The depletion of flora has forced vaidus to spend considerably more time and energy in collecting medicinal plants thus making them increasingly difficult to practise vaidki merely as a social service. Moreover, people now tend to visit them only when allopathic medicines fail. Even if they are completely cured by a vaidu's medicine, they follow the 'tradition' of not paying him, vaidus too follow the tradition of not asking for payment. In a society where status is increasingly being equated with money, vaidus are fast losing their respectable place in the community. All this has distracted the young generation from vaidki. In most cases, the

present generation is the last practising one. Various taboos have further restricted the transfer of knowledge e.g. the taboo on allowing a 'shishya' to part with information before his guru's death. Many learned vaidus have died without passing on knowlege to anybody. Thus, some valuable information has vanished for ever. Vaidki, today stands on the brink of extinction.

Vaidus' Organisation

Organising vaidus has been a great challenge for the group. Professional jealousy and mutual suspicion, complaceny, taboos on information–sharing, lack of lively contact with the outside world and prejudices among vaidus obstucted them from coming together. However, there have been some favourable factors too. The growing realisation of the gravity of situation by vaidus, consciousness gained through their experiences (direct/indirect) of organisation of EGS workers or on forest issues the ability of activist to relate individual/professional problems of 'development' and 'ecology' have helped vaidus to come out of their shells and join hands for a common cause. There have been several camps for mutual information sharing and frank discussion on common problems.

There are greater challenges ahead: initiating sustaining democratic processes of decision-making and implementation, evolving short and long-term programmes to give an expression to their organised might, cultivating a spirit of experimentation and enrichment of knowledge, arranging for their continuing education through interaction with other vaidus and experts in the field, carrying out field trials for verification of claims made by vaidus and most important, helping the movement develop independently without dependence on the activist group and yet retain its linkage with the wider struggles.

At present, the vaidus, on their own initiative have decided on the following programme : i) To spread organisation to a wider area. ii) To organise a series of camps — for information sharing on diseases and remedies discussion on common problems. iii) To set up a co operative for storage and processing of crude drugs (processed drugs fetch a much higher price) to directly bargain with drug companies so as to eliminate the middlemen. iv) Felicitations of senior vaidus at the hands of reputed vaidyas (ayurvedic practitioners) and making other efforts to create awareness in society about the role of vaidus.

The organising group wishes to try out a scheme wherein five acres of land obtained from the forest department under the Social Forestry Scheme will be used for cultivation of important medicinal plants. The cultivator will receive a small regular sum of money from the forest department for developing a forest on the land plus a part of the forest yield. This experiment, if successful, would help reduce the shortage of medicinal plants and also provide some monetary benefit. This may help to preserve the spirit of 'social service' intensely prevelant in vaidus. We believe that the spirit of selflessness is the one we wish to develop in tomorrow's society. So, this spirit already present in Vaidus should be encouraged. However, it is not yet clear whether it would be possible to nurture this spirit without their exploitation in present system.

It is difficult to say whether vaidus, long used to confirming to a particular system of healing will be open enough to freely discuss with others their understanding of diseases and drugs and perform experiments with scientific objectivity and make suitable changes in their practice. It also remains to be seen how formation of new forms of mystification of knowledge, and hierarchy could be prevented.

There are no readymade solutions to these problems. However, there is room for hope as experiences reveal the intelligence, innovation, scientific objectivity and passion for knowledge hidden in semi-literate folks. Natthuji's, is a glorious examole. An illiterate shepherd boy, he used to leave his cattle for grazing outside the school building so that he could overhear alphabets chanted by school children and revised them with help of friends fortunate enough to attend school. He learnt reading from the names of tins at a grocer shop. He cultivated his interest by purchasing books. He had the guts to experiment on himself and his son to gain confidence about his experiments. Today, he is assertive enough to tell the patient to choose between him and the doctor It is a pleasant surprise to see him at such an age, scan through books in search of new information. So, when Natthuji says, "Well, it's not impossible to build and sustain vaidu's organisation for peoples benefit", there should be at least some reason for hope.

POLITICAL-ECONOMIC-STRUCTURES — APPROACHES TO TRADITIONAL AND MODERN MEDICAL SYSTEMS

catherine a mcdonald

Abstract— The paper is concerned with the WHO-UNICEF suggestion to train indigenous healers to be first-line deliverers of medical care. Rather than evaluate this proposal directly, the paper concentrates instead on the factors currently influencing the relationship between indigenous and Western medicine. A framework, viewing the potential health impact of the use of indigenous healers, is constructed through the comparative method. [6] *Data reviewed consists of monographs, journal articles, dissertations etc., and considers historical, cultural and political theories of the status of native medicine. The paper concludes that the politics of health care is a greater impediment to the provision of "health care for all" in some types of political economic systems than in others. Thus events in the health care system are seen as influenced by the larger socio-political system. This article is reproduced from "Social Science and Medicine" 15A : 101-108, 1981.*

Introduction

Medical need in the developing world

The scarcity of medical service in most of the world is one of the factors affecting the health of the peoples of the earth. Although the outcome of medical care is greatly hampered by poverty, associated problems of malnutrition, poor sanitation, crowding and lack of education, the social and economic gap between the have and the have-not nations extends to the area thought to limit the destructiveness of disease and ill health. Bryant discusses this, perhaps more eloquently than others :

> Large numbers of the world's people, perhaps more than half, have no access to health care at all, and for many of the rest the care they receive does not answer the problems they have. The grim irony is that dazzling advances in biomedical science are scarcely felt in areas where need is greatest. Vast numbers of people are dying of preventable and curable diseases or surviving with physical and intellectual impairment for lack of even the simplest measures of modern medicine. Whatever the desires of nations to reach their people with health care, the actual task of doing so is extraordinarily difficult. It is difficult in Malawi, one of the world's poorest countries, and so is it difficult in the United States, one of the word's richest... [1,pp.X 51].

Country	*Expenditure*	*(%Budget)*	*Population/bed*
Jamaica	$9.60	11.0	240
Senegal	3.47	6.6	700
Thailand	0.60	3.4	1280

Health expenditures vary from between 56 dollars per inhabitant in the United Kingdom to 20 dollars in Indonesia. Eleven precent of Colombia's budget provides 3.50 dollers per inhabitant while 4.7% of the United States government expenditures means 47.40 dollars per inhabitant for health services. The meaning of this is clear in the preceding tabulation of number of hospital beds, whose definition can range from a canvas cot to an electric-powered special. The preceding and following statistics are from Bryant [1] for the period 1961-1964.

The discrepancy between urban and rural areas can exacerbate the problems of providing care. Part of this is due to personal reference:

> The reluctance of doctors to leave the big cities and go out to practice their profession in the rural areas is a long standing basic medical problem which Mexico has in common with all other Latin American countries [2,pp.262]

The result of this reluctance? A difference in the rural-urban physician ratio (1:3000 vs 1:500). This is not just a local phenomena. UNICEF-WHO estimate "that in a number of developing countries less than 15% of the rural population and other underprivileged groups, such as slum dwellers, nomads, and people in remote areas have access to health services". [3]

Another reason for rural shortages of medical services is lack of resources. Many of the underdeveloped countries are predominantly rural and, as our earlier comparisons showed, lacking financial resources even for urban areas.

At the University in Kampala, Uganda, the press of obstetrical patients is so great that the average hospital stay for delivery is less than 24 hr. At Sierra Hospital in Bangkok, Thailand fully half of all hospital admissions, 17,000 of 34,000 in 1 year, are to the obstetrical service. But despite the overwhelming numbers of obstetrical patients in these two institutions in these countries at large, less than 15% of all babies are delivered by trained personnel [1, pp.41].

Thus, the provision of medical services to all is a problem, particularly so when the lack of resources is coupled with attempts to provide doctor-hospital Western-style services to rural areas.

Indigenous medicine

The previous discussion neglects the presence of medical services in all socio-cultural units, Bryant[1] and Schendel[2] note the influence of local healers and the belief in magical medicine. Bryant notes that accessibility of care and reduced social distance are also factors in their utilization; Lee[4] points out that in Hong Kong it is easier to find a Chinese practitioner (4506) than a modern physician (2317). By deduction we realize, when Bryant tells us that only 15% of a nation's babies are delivered by trained physicians, that the other 85% are assisted into this world by someone (usually, but not always, by someone other than the mother). Stromberg stresses the reliance on local healers in Ghanna for the 70-80% of the population living in rural areas. He states that the absence of modern health facilities, in Ghana as in other countries, does not mean there is a vacuum in the rural areas,

> ...as in many other countries, traditional birth attendants, healers, herbalists, and practitioners of various types exist in most villages and treat many diseases and other health problems....thus there is a health care system throughout the country which is consonant with traditional beliefs and practices [5,pp. 15].

WHO-UNICEF[3] agree and suggest the different types of indigenous healers may be trained and integrated into the general health system.

This solution seems like a panacea. Given the shortage of medical dollars, personnel, and facilities, problems of transportation, the social and cultural acceptability of new ways, *why not* train indigenous healers to care for the medical needs of their communities? The someone delivering 85% of two countries' babies might benefit from training. Furthermore, most of the medical needs of the world are not complex :

> It involves recognizing threats to health that are visible and monotonous : malaria, diarrhea, pneumonia, bilharziasis, hookworm, malnutrition, tuberculosis—or problems that are less a threat and more a personal concern : leg-ulcer, earache, constipation, headache, broken finger, inflamed eye [1,pp. 61].

Given the potential for traditional healers to provide health care that is affordable, accessible, culturally relevant, belongs to the people, and has the possibility for serving as a conduit for new ideas in areas other than medical—what factors influence the relationship between it and modern medicine? There are several theoretical approaches that may be taken. To answer the question, why not utilise indigenous medicine, it is also necessary to investigate the imbeddedness of the current relationship between modern and traditional medicines in the social system. That is, various factors have led to the exclusion of native healing systems from most modern medical systems. What are these factors? How might they relate to the utilisation of native medicine in a modern setting? What happens to the indigenous medical system as a nation Westernises (modernizes, industrializes, develops)? This, then, the factors influencing the utilisation of indigenous medicine, is the focus of this paper. But first, the methodological issues must be discussed.

Toward a framework—the patched-up design

To answer the question, what factors have determined the status of native medicine, requires a comparative approach. Factors thought to be explanatory for one time and place can be shown to be epiphenomenal and hence irrelevant in another. We will find in the next section that the integration of modern and traditional medicines has varied from one country to another. Why? Cross-national comparisons of health systems is one method of looking at health services organisation.[6] This approach is, however, fraught with difficulty :

> Those engaged in the study of comparative health service systems still struggle with problems of theory, method, and standards for cross-national research. In addition, the available data are too often fragmentary, unreliable, non-comparable and subject to political constraints [7,pp. 278].

Elling (see also Elling and Kerr[8]) has introduced a method for cross-national comparison — the method

of contrasting case studies :

> Given the controlling character of the societal context, the concluding point of this brief introduction to the contrasting case studies framework will be that inferences about health services organization may be culled broadly from sharply contrasting systems, but it is likely that cross-system applications can occur only between those with somewhat similar levels of resources and similar political structures [6,pp. 268].

The principle behind this is elegant. The *method of difference*, as expounded by John Stuart Mill is one of his four types of evidence that can be used as evidence for a causal relationship, or in our case, to control for extraneous factors. It states that if various situations have all factors in common but one, that may be regarded as the causal factor.[9] Elling and Kerr[8] found that this principle could be used to identify countries that are over- and under-performers in health, wealth and education levels being similar. The comparative approach will be used here. In other words, possible explanatory factors will be tested by the method of difference for one set of countries; eliminating these, we will then discuss other factors elsewhere. This approach is not without dangers. Campbell and Stanley [10] discuss the dangers inherent in experimental design. They are critical of this type of comparison, stating that it does not control for the selection of the groups to the initial purported causative factor or the loss of groups from this factor. More simply, there is little way of knowing what additional factors are responsible for the initial conditions. They describe a more refined variety of this model as a patched-up design with an inelegant accumulation of precautionary checks. The defense of this approach is twofold : First the world refuses, at least thus far, to be standardised to the interests of science; second, it must be asked if the lack of strictly comparable evidence is to limit the questions we may ask. This is addressed by McGranahan [11], who considers that perhaps cultural and social diversity is too great to permit international measurement. He feels that the need for data in formulating international social policy dictates continued comparative social research. It is the wish of this author that reports of this type, where quantification is deemed unnecessary or impossible, are, if not totally accepted, a stimulus to the further refinement of hypothesis of a broad perspective.

Factors Influencing the Use of Indigenous Medicine

Culture and progress

Galdston[12] differentiates between medicine as the science and art of healing the sick and caring for the well (a body of knowledge), and medicine as the practice of that science and art (the performance of a profession). The relationship or lack of it between traditional medicine and Western medicine is dependent on both parts of this definition. Medicine as a body of knowledge will be discussed in this section; the professions of medicine in the following section. This paper has not differentiated between the various types of native healers or different levels of theoretical complexity of medical systems as suggested by Marchione.[13] In contrast, Sigerist feels that all systems of medicine contain basic underlying similarities:

> There can be no doubt however, that primitive medicine, as it appears within the various culture patterns, consists of a relatively small number of elements, which are very much the same in all primitive cultures and vary only in their combination [14, pp. 121].

Marchione [13] states that distinctions between three types of indigenous systems may affect the reaction to it by society and other professions. The next part of this section demonstrates the reverse of relationship suggested by Marchione who sees full-time practitioners of great medicine accommodated and given support while part-time practitioners are ignored, and folk healers tolerated or opposed. We discuss three systems on an equal level of complexity. Thus, this factor is controlled for. Yet, any future attempt to integrate a native healing system into a modernising one would be well-advised to consider the characteristics of the native system, for more practical and mundane reasons.

Most studies of health care systems avoid the traditional (e.g. Weinerman [7]) or give it minimal attention, regarding it as a survival from a more primitive, less scientific, time. Attention is focussed on the scientific progress of medicine such as is suggested by Galdston:

> History is a progression of ideas, traced along a circuitous path [12, pp. 3-6].

Garrison [15] is kinder and suggests that folk medicine brings the peace of security against the fear of the unknown. Folk medicine also has its defenders. Dr Bocan Alpha Ba (International

Conference on Health and Health Education) believes that "traditional medicine deserves respect".[16] He states that African doctors turn to traditional arsenals when supplies of Western pharmaceuticals are short. Green [17] comments upon the astonishing technical efficiency of primitive surgery, given the most ancient instruments. Sigerist observes that little medical progress has been shown in some areas:

> This history of the therapy of cancer is very dull. The principles we are following today, namely the elimination of the tumor as radically as possible, were discovered in far remote antiquity. Our operative methods are much more efficient than theirs were, and besides the knife we have X-rays and radium to destroy the tumor cells, but we have not found any new principles yet [18, pp. 62].

One view is that traditional structures are inferior in all ways to modern medicine and are used by only the poor or ignorant: Banerji.[19] notes that the inhabitants of his native land prefer allopathic (Western) medicine irrespective of social, economic, occupational, and regional considerations. Cost and accessibility of services were the two major constraining factors. Local healers were used for minor illnesses or when Western medicine failed, Lee[4], however, points out that in Hong Kong the correlation between utilization of modern medicine and wealth ($r = 0.68$) was in the same direction as between Chinese medicine and the wealth of the area ($r = 0.54$). Futhermore, it seems that people choose rationally between the two on the basis of perceived effectiveness for symptoms. Although the exact statistics were not provided, the younger generation was said to make more extensive use of Western medicine.

An approach that makes the assumed inferiority of traditional medicines more explicit is the historical approach. This approach stresses the evolution of medicine, both empirically and conceptually. Garrison[15] observes that the advancement of medical science is the history of the discovery of a number of important principles leading to new views of disease, to the invention of new instruments, and to the development of a rational scientific concept of disease, not as a demon but as an altered physiology. Kuhn[20] critiques this view, rejecting the accretion approach to progress while retaining the concept of the progress of science. This approach fails to note that most medical systems have performed adequately for the cultural level of the people. Furthermore, some have been medically effective. Bernado Ortiz de Montello found that 16/25 of Aztec drugs produced the desired effects, 4/25 were questionable, and 5/25 were not good enough.[21] Knowlege, then, is not exclusively Western.

It strikes one as strange that the social and psychological functions of medicine are given stress only for the primitive versions. All medical systems seem to function to allay fear of death and infirmity through professionalism (elitism), and in this sphere shamanism differs little from white-coated magic. On the social level, there is evidence that the theoretical perspective of medicine relates to its functions as an integrative institution of society. When society is held together by fear, medicine is synonymous with witchcraft and magic; as religion becomes dominant, disease and sin coincide; later, in a rationalist society, science is the new god: from temple to cathedral to medical center.

Another explanation for the apparent decline of traditional medicine is closely related. It suggests that the populace rejects it in favor of more modern medicine, or is it retained due to their ignorance of poverty? Sigerist[14] suggests that the development of magical-religious medicine in Greece was a result of the needs of the indigent sick. Lee[4] points out that economic factors influence the distribution of Chinese medicine. Harwood[22], Logan[23], Martinez and Martin[24], Rubel[25] and Snow[26] provide evidence of the continuing utilisation of native healers by populations of Mexican Americans, Arizona Blacks, Guatemalans, and Puerto Ricans, Schendel[2] traces this cultural lag to superstition, while Foster[27] cites the cultural barriers to change. However, DeWalt [28] is able to show that the use of native curanderors (curanderas) in a Mexican village is the result of a rational process of choice related to the nature of the illness.

How important is the progress of medicine as a factor in determining its role in modernising societies? Is it only the internal characteristics of a medical system that determine its fate? A cross-cultural historical study by Leslie[29] sheds much light on this topic. He shows that traditional medicine in three countries, China, Japan, and India, sharing somewhat similar cultural factors, had a different fate in each. He shows also that the Greek, Ayurvedic, and Chinese medical systems share similar internal characteristics—they are based on humoral theories, have standardised learned practices, long periods of training, codes of ethics, and claims to social status. Yet their incorporation

into modernising medical systems varied. In Japan, the ruling elite adopted modern scientific medicine as the legally sanctioned system. In China, the incorporation of traditional practices into an essentially Western system occurred. In India, a dualistic, though not completely equalistic, system developed. Thus, neither cultural nor internal characteristics of medicine account for this difference.

Another theoretical explanation for the status of traditional medicine is seen to be the organisational struggles of medical professions :

> A characteristic of modernizing societies is the co-existence of modern and traditional professions that claim to perform the same function for the society. As a result of differential support by the dominant classes and their social values and by the academic and political authorities, the modern profession occupies a higher statification ranking than the traditional professional [4, pp.60].

The theory of professionalism, the organization of medicine, as the explanatory factor, for the survival or lack of survival of traditional medicine will be discussed in the next section.

Theories of professional struggles

Much of the work in cross-national comparisons of health systems ignores the political-economic level of organization intermediate between macro-processes (society) and micro-processes (persons). One notable exception to this is the study by Carboni[30] of the formation of a geriatic speciality in the United Kingdom which has not occurred in the United States, to date. Carboni traces this to the division of medical territory by the medical profession in the UK rather than to a more rational, knowledge-based division of labor, an explanation suggested by Stevens[31], for example. This division, then, was based in political processes within the profession to the end of controlling medical resources (wealth, patients, and control over an area of service). This approach has been offered by Berlant[32] as a framework by which to understand the rise of allopathic medicine in the United States. Before examining this approach, it is necessary to mention that the view of individual practitioners may diverge from the organisations perspective Blum[33] found both acceptance of the significance of local healers and rejection of their existence by physicians in his study of a rural Greek town. One famous healer had even hired a physician and X-ray technician to work as his assistants. This occurred despite government and professional opposition to quackery.

Berlant[32] describes the process by which the AMA organized and defeated its medical rivals. He critiques Parson's characterisation of the medical profession as a normative structure, based on idealised beliefs, regulated by a system of social controls, and whose function is to maintain healthy actors to fulfil social roles. Instead, he uses an historical approach, coupled with Max Weber's theory of monopolisation, to show that many of the practices of the medical profession function to increase the power, prestige, and wealth of the profession collectively, regardless of the benefit to society or the individual patients. Weber s theory of monopolisation states that :

> The success of a group is a function of two broad determinants of economic action: the group's tactics of competition (or of conflict) and the conditions of competition. One major but not exclusive condition of competition in modern society is the state, which exercises both authoritative and de facto domination over groups within its territory [32, pp.17].

The tactics of the AMA will be discussed here; the role of the state in the next section. The elimination of external competition is accomplished by two means, according to Berlant.[32] The first, which he sees as the dominant methodology employed by the AMA, is to bring the "force and prestige" of the legal and political community to bear against competitors. This involves licensing and educational restriction. The goal of this strategy is to restrict financial support to one's opponents. The second method is to challenge one's opponents on ethical grounds, thus challenging their symbolic integrity (image).

The second game, that of name calling was practised by both sides:

> The AMA (circa 1924) referred to all nonconformist healers as "sectarian". Its Judicial Council has defined this term to include any practitioner who follows a dogma, tenet, or principle based on the authority of its promulgator to the exclusion of demonstration and practice,
>
> ...Abraham Flexner, the eminent authority on medical education, contended that homeopaths, eclectics, physiomedicals, and osteopaths might rightly be considered as sectarian rarher than fraudulent practitioners, since they all believe

that anatomy, pathology, bacteriology, and physiology must form the foundation of medical education but regarded chiropractors and mechanotherapists as no more than unconscionable quacks.

.. In charging that conventional practitioners laid undue stress on chemical compounds and surgery; these groups, with some justification, considered regular doctors as sectarian [34, pp.2-3].

Despite his moderate stand toward the variety of medical practitioners, Flexner's report on medical education (1920-21) proved to be the coup de grace to most non-regular medical practice. Stevens[31] speaks of the reluctance of the general public (USA) to use the modern (regular) physicians because of their harsh treatments. They were popular as a status symbol among the urban rich, due to the prestige of their European education. Burrow[34] claims that the battles of the AMA to control licensure and restrict entry to and the proliferation of medical schools was against quackery.

Berlant views the demise of the sectarians as casualities of the internal battles of the AMA. He considers the number of irregular practitioners too small to be considered a threat, at most 10% of all practitioners. Estimates of the numbers of homoeopathic practitioners are 2400 between 1835 and 1840. At most, there were some 7000 sectarian practitioners in the 1845—1860s as compared with some 20,000 orthodox medical graduates and another 40,000 non-degreed orthodox matriculants. This was the real threat : the rapid expansion of medical schools and the large number of educated physicians. Six medical schools in the decade 1810—1820 produced 100 graduates out of 650 students; this increased so that by 1860 there were 13 schools comprising 4500 students and graduating 1300 in the 1850—1860 decade. [32]

Berlant describes the tension between academics and practitioners for control of the medical profession and licensure. Medical societies were formed in the 1760s and not until 1783 was a medical school, Harvard, the first serious candidate for establishing the qualifications of a physician.[31] The AMA, established in 1847, soon reached a compromise position with the development of a licensure plan whereby a diploma was not an alternative to licensure but a pre-requisite. It then proceeded to regulate the supply of medical schools and hence physicians [32]

The growth of medical schools had been phenomenal :

> In 1869 according to the Bureau of Education there were 72 medical colleges in the US, 59 regular, 7 homoeopathic, 5 eclectic, and one botanic... (By 1911 every city had their schools) 39 in Illinois, 14 in Chicago, 42 in Missouri, 43 in New York City, 27 in Indiana, 20 in Pennsylvania, 18 in Tennessee, 20 in Cincinnati, 11 in Louisville...one physician for every 691 persons in the United States contrasted with 1:1940 in the German Empire; 1:2120 in Austria, and 1:2834 in France (circa 1913) [15,pp.761-763].

The AMA responded to this by supporting two investigations of medical education. The first, run by a physician, raised an uproar, but created little change. The second, headed by Flexner, led to reform and the securing of a medical monopoly by the AMA. Stevens [31] sees the impact of this report as largely financial; foundation money from the Carnegie Foundation, General Education Board (a Rockefeller Foundation), and other sources enabling the better schools to improve while others declined due to lack of support.

The role of government

As discussed earlier, Weber considers the role of the state as one important condition in the survival of an organization. Leslie's cross national historical account. "The Modernization of Asian Medical Systems",[29] stresses the influence of government policy. He shows the Japanese ruling elite adopting modern scientific medicine as the legally sanctioned system. The Chinese incorporation of traditional medical personnel and practices swings with the pendulum of political change (Wolstenholme and O'Connor[35] : Harbison and Myers [36]; New and New[37] ; and Sidel and Sidel [38]). In India, the ambiguity of government policy has led to dual medical system.[19] Lee[4] details the parameters of environmental support in Hong Kong. The government employs one-quarter of the modern, but no Chinese, physicians. Anyone can practise Chinese medicine without a licence but there is a registration fee of twenty-five dollars. The practices of Chinese physicians are restricted. They are not allowed to issue death certificates, to use medical titles, or to use certain restricted medicines. Schendel[2] describes the incorporation of Spanish and Aztec medicine after the conquest (Cortes) under royal orders, and the diffusion of Aztec pharmacopoeia into Europe. When Germany passed a statute on June 21, 1869, abolishing some of the physician's obligations, the result wes an increase in the number of nature and faith healers.[15]

Berlant considers that the growth of the AMA and its monopolistic advantages were linked to the rise of state power which was then able to bolster the power of the profession. He then asks what is the advantage to society of allowing monopolization. He feels that an explanation in terms of the public interest is not convincing in light of the differential distribution of the benefits of medical care and he suggests an alternate explanation that is reminiscent of Duff and Hollingshead[31]

> Particularly in the United States, the development of the medical profession has been closely tied with the development of stratified relationships between social groups, so that quality medical care has tended to be a prized scarcity and an object of class behavior [32, pp.505].

This explanation is good but medical care as an object of class behavior does not tell enough. Elling[40] sees a close relationship between the nature of society and the nature of the health-medical systems.

It can be demonstrated that there is a correspondence between support of the indigenous medical system and the type of political system that exists. Elling (personal communication) has suggested a typology of countries along two continua — the centralised-decentralised power dimension and the concerted-pluralistic action dimension. Thesec oncepts refer to the general nature of the formal (centralised decentralised) power structure as well as to the informal (concerted, pluralistic) dimension of power. It is possible to assign countries to one of four cells as in Table 1.

Table 1. Political structures

	Centralized	Decentralized
Concerted	USSR	China
Pluralistic	India	USA
	Mexico	Canada
	Japan	England
	Hong Kong	

Table 2. State support of indigenous medicine

Type of Support	Country			
	Japan	China	India	USA
Symbolic	Medium	High	High	Low
Financial				
Educational	Low	High	Medium	Low
Research	Low	High	Medium	Low
Practice	Low	High	Medium	Low
Legal				
Licensing	High		—	Low
Education	—	Medium	—	Low

Table 2 shows the varying degrees of support that a medical system may receive along different dimensions. Scores of high, medium, or low reflect action taken relative to that of other countries. Symbolic support is defined as actions taken by the government of a country to preserve indigenous medicine as part of the heritage of a country. Japan is rated medium, not because it has considered its medicine a heritage[29] but as compared to the United States, there has been little persecution of indigenous healers[41] China[29] and India[19] have recognised the cultural roots of their medicines. Japan provides no funds to native medicine but does require licensing of native practitioners[42], thus granting them recognition and legitimacy. China does support traditional medicine financially but not at the level of modern institutions.[29] Licensing of medical practitioners was abolished in China along with the leveling of other professionals, but traditional institutions have received government recognition. India has made some grants available for the study of Ayurvedic medicine and the provision of services[19] A subjective guess would be that it is less than that provided in China. Regulations for licensing of medical practitioners and traditional schools are currently being decided in India (communication from Pandit Shiv Sharma, in visit to UCONN Health Center in 1975). These countries contrast with the United States where non-modern forms of healing receive no support.[43]

How does medical care in a country relate to the form of goverment? We see from Tables 1 and 2 that only the United States, a decentralised, pluralistic country has provided no support to any but the most politically powerful medical organization. This is the result of a system where health is not a national priority, where there is no system, program, or prioity of expenditures for health. It appears that only centralized and/or concerted countries refuse to allow the battles of professionals over the carving up of the medical arena to interfere with the delivery of health. Bryant[1] makes the point that health programs can also be divided among government agencies. A few examples will

suffice. Current philosophy in China dictates that the purpose of the medical and educational system in china is to serve the people.[44] In fact, it has been noted that one problem of Chinese education is its overly ut litarian nature.[36] This signifies not the absence of professional politics but their subordination to national policy. This has occurred also in Russia where feldschers were employed despite professional opposition[15]; in India where Ayurvedic physicians have not been embraced by the medical establishment[29]; and in North Vietnam were Western and Oriental medicine is being combined.[45]

Conclusions

This paper has discussed some of the factors influencing the status and utilization of native healing practices in the modern world. Though cultural and internal factors may affect the utility of traditional medicine by encouraging bad practices and discouraging new ones, it is equally certain that this medicine of the people contains effective practices and new ideas. Thus, the links between it as a knowledge system and its role in medical system has been tenuous. The role of professional struggles in the medicial arena as the dominant factor has been tempered by the Influence of government where it has been able to direct medical priorities. It has been suggested that in centralized governments or in those where action is concerted, the government is able to set priorities; in other situations, such as the United States, health priorities are the outcome of professional struggles.

From this, it is evident that the outcome of employing traditional medical structures to meet the health needs of the world will depend to a large degree on its interface with professional organizsations and the type of relationship it has with the government, either controlling or controlled.

The question, however, remains unanswered. Why do different kinds of political systems allow their policy or lack of it to benefit medical power groups? Several different models of the articulation between the medical system and the political system exist. Krause discusses the imbeddedness of the health system at several levels: The first is the level of values —

> First there is the issue of occupational ideology inherent in the term profession itself. What citizens believe the medical profession to be determines how they act in accordance with this belief [46, pp. 36].

Friedson[47] agrees with this view and criticizes the medical profession for usurping values when their claim to power is technical expertise. We suggested earlier that the relationship of medical systems to political systems was not due to cultural factors such as the state of knowledge of the profession or acceptance by the local residents, but rather to the nature of the relationship between the health professions as organizations and the form of government. We also noted that symbolic support is one means by which a profession may survive and obtain other types of support.

Krause[46] also suggests that control over the delivery of health services varies according to the ownership and control of health service production. This theme is explored in greater detail by Navarro, who makes the point that physicians no longer control the health system through the power of their knowledge. Primitive, or what Navarro calls competitive capitalism, has given way to monopoly capitalism : Health is the ...

> ... second largest industry in the country... the flow of health insurance money through private insurance companies in 1973 was 29 billion dollars slightly less than half of the total insurance — health and other — sold in this country in that year. About 515 billion dollars of half of that money flowed through the commercial insurance companies... [where] we find again a high concentration of commercial capital [48, pp. 150].

Navarro continues that the same corporate interests which control the American economy also dominate the health sector. Although physicians qua physicians are losing Influence as the source of power shifits from entrepreneurial to corporate sources, physicians still remain part of the dominant class in terms of economic position and many are now members of the corporate class. The medical system is one way to reinforce the values of and contribute support to capitalism.

Elling (personal communication) suggests that it is this context of the health system that in the end determines if the utilization of traditional medicine is to be of real value or if it is to be a delaying action to perpetuate second-rate medical care. Professionalism, coupled with a stratified society, can serve to thwart the intention of the use of indigenous healers — the provision of better medical care. Thus we find a rural midwife program in Arkansas training women for rural service.[49] But

in fact this program is designed to preserve a two class system of medicine whereby the rural poor mostly black, are receiving minimal care, with little or no access to special services while the wealthy white are treated in medical facilities by doctors reluctant to serve the countryside. Or there is the paradox that is now occurring in India, where the use of indigenous practitioners will mean less available medical care As a by product of their struggle to achieve recognition, Ayurvedic medicine practitioners have agreed to limit the number of practitioners they will certify and train. The price of legitimacy and other support is diminished service to the population. One must question, then, the use of indigenous healers — who is to benefit? — and who is to gain? Their utilization cannot be separated from the influence of the medical system and its position in the socioeconomic and political systems of a country.

'GREEN REVOLUTION' AND HEALTH
Changing Patterns of Health in Nanded

sunil dighe

The green revolution and the changing patterns of agriculture have resulted in a deterioration of the health status of the people. The health services are a source of exploitation in one way or another. In the meanwhile, the rich tradition of herbal medicine is disappearing through disuse, which is itself a result of changes that have occurred in the wake of the green revolution.

"The condition of the working class is the real basis and point of departure of all social movements of the present because it is the highest and most unconcealed pinnacle of the social misery existing in our day", (Preface to *The condition of the working class in England* — F. Engels).

Every major or minor change in system has raised the hopes of improvement in the lives of the poor and created illusions about the present process of development. New policies have been drafted and redrafted at the international and national level to eradicate poverty and to change the lives of the 45 crore poor people living below the poverty line. But no significant change has taken place. As admitted by then World Bank chief Mc Namara in his 1973 Nairobi speech, the problem of the world's 800 million poor people has remained unsolved.

The new approach of attacking poverty began in 1975 on a world scale and in India also. New schemes of rural development to eradicate poverty were introduced. And their health was given importance. It was a target-oriented package programme. What is happening in the country side since 1975 is worth studying.

Although the green revolution began in Maharashtra since 1965-67, its spread and growth is now restricted. Thus the problems have increased and the crisis is accentuated. The old picture of village life is not found now. Alongwith the deteriorating socio-economic system, we find the health of the people is very much affected and has deteriorated.

The area under study is Biloli taluka in Nanded district of Maharashtra. The district is divided into eight talukas and among them Biloli has the highest levels of irrigation. Most of the irrigation schemes were completed by 1975. There are three medium irrigation schemes functioning in the area. Total population in the district is 17,47,589 spread in 1388 villages. The major crops grown are jawar, wheat, rice, cotton, chilli, and now sugarcane. Seedplots producing cotton seeds are situated in highly irrigated area. Even banana plantations are ample in number. This area is wellknown for producing long staple cotton. Now, four sugar factories are producing sugar and alcohol. Out of these, one factory is in Biloli taluka.

Changing patterns of agriculture : Effects on health

Due to changes in the cropping pattern and switching mainly to cash crops like sugar cane and cotton the production of foodgrains has declined in the area. So the old system of cropping, mixed-cropping, is disappearing. Turmeric, another cash crop was uprooted firstly in 1972 drought and by the government policy to favour supply of water to sugarcane. Similarly, ground nut is not favoured by the government. In 1983-84 canals became dry due to water-shortage. And though the government initially announced guaranted irrigated water to groundnut crop, only once or twice did the canal receive water. So all the groundnut crops of middle and poor peasants were destroyed. The rich could irrigate with the help of powerful electric pumpsets. In non-irrigated area chilli is still grown. But in irrigated fields, chilli crop cannot be grown now as the land is saturated with water which is not suitable for growing chilli.

There is significant decline in the area under pulses. Partly because there is no increase in the relatively low per acre returns. Another difficulty with the pulses is that it cannot be grown with hybrid kharif jawar. This is a short-duration crop. This reduction in the acreage under pulses has cost a lot to the village poor because, pulses used to maintain the fertility of the soil (nitrogen fixation). And people used to have their balanced diet. As the diet mainly consists of hybrid roti, sometimes, rice and watery dal (mainly tuar or udid), their

diet has not remained a balanced one as it used to be. Other crops like sweet potatoes which used to be poor man's emergency staple food, have also disappeared.

Thus, we see dependence of people on cash crops resulting in a decline in pulses production. This change in crops pattern has increased dependency on high cost chemical fertilizers and upset the traditional soil preservation mechanism and resulted in decline in the health of the people.

Anti-people forest policy

The present forest policy of the World Bank and the government has contributed to the destruction of agricultural people's living conditions. All the old variety of trees, like malwa, kath khair, sag, bamboo are not planted by the forest department on a large scale. Instead, subabhul and eucalyptus are planted on a large scale with the result, more wood is supplied to the paper mills and groundwater shortage has increased. Many old varieties of the tree had medicinal value and herbs used to grow around them. Their disappearance has created an acute shortage of such country medicines. Even in villages, old tamarind trees have disappeared. People are using less tamarind in their diet. The effect of this new forest policy on the ecosystem is tremendous.

It has also affected agriculture, since wooden implements depend upon the forest. The new varieties of trees are not suitable for house construction or cutting the implements from wood. Even firewood shortage has become most acute. People burn any type of shrubs and wood for cooking purpose even though it is unhygenic. They have to spend more time in collecting firewood. Due to shortage of wood, the size of the huts are getting smaller and narrower which is again unhygenic. The result is diseases like asthma, cough and other respiratoty problems are rampant. Old chullah still exist even though tractors and high yielding varieties are introduced by new technology. The chullah creates pollution problem within the huts.

Due to increase in the cost of living, all the earnings of the family members are spent on only survival. The cash economy has changed the situation considerably in this area. As the saving of the poor is virtually nil, for sickness expenses, they have to borrow from landlords, rich peasants or money-lenders.

Plight of non-agricultural workers

Those who work on State Employment Guarantee Scheme (EGS) as labourers, are supposed to get as per law medicines if they become sick on duty. They must get drinking water at the worksite. Usually, the worksites are far away from the villages. Most of the time, EGS workers do not get ordinary medicines when they get headache or fever, or if an accident takes place even first-aid boxes are not available. At site they get contaminated water for drinking which causes waterborne diseases. This is rampant in the area resulting in loss of several mandays due to sickness. The law has made a provision for shelter and cretches at worksite. But rarely are these provided. We find infants and young babies are looked after by small children while the mother is working on the site. Last year a labourer died on EGS site in a village in Biloli taluka due to both starvation and sickness. (This matter was discussed in the Maharashtra Assembly). The reason was that he had not got his wages for more than fifteen days.

The sugarcane factories also pose new problems. The molasses accumulated near factory creates pollution problem for the peasants living near the factory. Water-pollution by the sugar factories is so much that many deaths have taken place in the villages near the sugar factory. Sudden death of animals after drinking water is quite common in the area. Even the hue and cry made by the press and organisation does not affect the sugarbarons and they continue to violate all anti-pollution norms. The health condition of sugar-factory workers is equally bad. They are exposed to pollution, chemicals and accidents due to outdated machinery.

Certain other factors also affect the health of the people. Adulterated edible oil has brought new types of diseases. Sometime ago strange kinds of jowar and wheat (imported) were distributed through the rationing shops. And after consuming them there was a virtual epidemic of skin disease. Similary, the imported wheat from US under PL 480 brought another variety of Mexican seed grass, which has since spread all over. This has made the land infertile and constant contact with the grass, spreads skin allergies and allergies affecting the respiratory system. (This is popularly known as 'Congress grass' and during 1975, Cong I Govt. banned the word 'Congress' grass).

Due to inflation, people tend to cut down

expenses on food items. For example, as the price of edible oil has gone up, women are using less quantities of cooking oil, not even using coconut oil for their hair. As the prices of medicines have gone up, ordinary tablets for usual ailments cannot be purchased by the people. This taluka has a very high incidence of leprosy, but only one leprosy centre is functioning.

Imperialist technology has improved HYV jowar, bajara, wheat and rice production in irrigated area but no breakthrough has been so far made on oilseeds and on HYV seeds for dryland farming. Thus, it has limited results for total agricultural growth in India.

Exploitative health care services

Medical facilities are available, for example in four big villages in the taluka. In this article we will look at two places : PHCs at Naigaon and Ketur. About hundred villages are connected with these centres. They are situated either at taluka head-quarters or at the villages where the most influential local MLA, ZP president or MP is based. The corruption at government dispensaries is so rampant that people tend to go to private doctors or the government doctors treat patients privately.

During the drought of 1980 and floods of 1983, various types of epidemics spread in the area. The government dispensaries and hospitals created such a situation that patients were sent back on the pretext of a scarcity of medicines. Kashtakari Sanghatana had to take up the issue, the doctors and dispensary staff were gheraoed for several hours. Only then was proper treatment given to the patients.

At the grassroot level, village health workers are operating. They are supposed to distribute medicine for ordinary ailments, malaria and so on. They are supposed to help mothers at the time of delivery. And to report to the PHCs when cases of epidemic or serious diseases are noticed. In the recent drive for birth control, they have to bring cases for family planning operations. Now it is lucrative business for them since the government gives monetary incentives to both patients and health workers. But generally stocks of tablets are not available with them or instruments are not availbale with them So people have to go to private doctors paying more fees or to the quack doctors.

The local organisation had to take up another issue since it affects the health of the people — "Bhanamati" (ghost or spirit) is a usual phenomenon and mostly women are 'haunted' by this in the villages. In reality, they are either psychic patients or ailments developed due to insoluble personal or domestic problems of feudal character. Many a time, patients became victims of superstition. So the local organisation had to takeup several cases and treat them in the Hospital after prolonged persuation. In the past five years, more cases of bacillary dysentry, flu, malaria are reported in the hospitals. Thus, even the health services have become a source of exploitation and people are not benefited though all the institutions are aided by government and international agencies.

Health under Green Revolutions

Changes have occurred in the attitude of the people towards health and medicine are quite obvious.

(a) All the old herbal, country medicines have disappeared and the trend of widespread use of allopathic medicines has been stabilised. It is known that the sarpgandha herb is used for serpina tablet for blood presure or heart problems Similarly, some old medicines based on herbs and minerals are quite effective. But little further research har taken place.

(b) Due to hard work, hectic life and mounting problems, people tend to ignore their health unless health problems become serious when they go to the doctor or the dispensary. Again less attention is paid towards the health of women and girls in the villages.

(c) Use of outdated medicines in the dispensaries is quite normal. As the efficacy of the medicine is automatically reduced, people have again turned towards either quack doctors or towards superstitious practices.

There are certain voluntary agencies like Oxfam which are working in the same villages where we are working. But they have not yet taken up any programme for healthservices. Except making propaganda for family planning operations (on the same line as the Government propaganda) they have done nothing in the health sector. The only service they offered to the people during floods was to give loan on low interest rates to the affected people and the loan was repaid by the debtors after the harvest. The huge irrigation schemes began only after World Bank aid arrived since the Government had no funds to provide them under the five year plans. So boosting irrigiation. new

technology of HYV seeds in irrigated area, boosting production for cash crops mainly for export, development of infrastructure and absorbing non-farm population in service industry, creation of well-knit finance organisations and so on makes the entry of forces of imperialism in agriculture on a sound basis and allows the local exploiters, landlords and rich peasants, a share of the surplus. But has it really solved the problems of the people?

Nanded is a drought prone area. In the past five years it was twice declared drought area and twice the area was declared as being flood affected. Instead of giving water for subsistence crops, water is given mainly to cash crops. Due to faulty man-made forest policy, the pattern of rainfall is changing and affecting the crop production and ultimately the ecology. All drought-prone areas eradication schemes are slowly turned into implementing a policy for export led growth, cash crop growth. This is happening nationally, locally under the guidance of imperialism. "A major plank for ambitious political leaders is the promise of providing irrigation to newer areas. Here the chief consideration is bringing prosperity to those peasants who are in a position to grow cash crops and not tackling the droughts."

Though agricultural production of HYV has increased, we do not find any improvement in the conditions of poor people. All the benefits have gone to the upper classes. Consequently, economic conditions of the poor have further worsened This has made health of the poor people a severe problem. The vicious circle of poverty and health can be seen clearly in the rural area.

What imperialism does to the system is that it has made the system totally dependant. Future growth and internal growth of productive forces is stopped or growth is stagnated. In the case of health, it is clear that no funds are made available for further resources and production of medicines on specific disease or health problems. The less costly methods of production of medicines for such diseases are not found out. Ultimately, as agriaculture is very important to extract surplus, imperialist and multinationals do make high profits on the deteriorating conditions of health. And thus country's real wealth, the precious people, mainly working force, has again been ignored and is subjected to the process of pauperisation. From slums to farms, the fate is the same in this system.

ORGANISING DOCTORS: TOWARDS WHAT END ?

anant phadke

Until the 'sixties almost all doctors in India belonged to the classical middle class, owning and controlling their instruments and cnoditions of production. But since the 'fifties more and more doctors are entering government service. The article begins with a discussion of the role of the wage earning doctor and suggests that the strategies for organising doctors should be based on a clear understanding of these contradictions.

This article was held over from the issue focussing on 'People in Health Care' (SHR II:2), due to lack of space. The author has since added a comment on Sujit Das's article in that issue which is published in the Dialogue section.

Analysis of role of doctors' organisations in social revolution in India, would require, to begin with, some analysis of doctors as a social layer (including an analysis of different subgroups of doctors) in India. This, in turn, would require an analysis of the role of doctors in the social process of production.

Materialist analysis of position of doctors

It is generally not recognised that although a doctor's work has its own peculiarities, it nevertheless involves a material process of production. Like the work of a barber or a massager, it brings about a material change in the human body and restores it to a 'normal' level. The 'raw material' on which doctors work is very peculiar — it is a material which thinks, has emotions and the emotional aspect is very much in action, when the body is impaired. This is especially true when the illness is serious. Hence the ideological-cultural relations that inevitably accompany any material process of production are much more pronounced in case of this material process of restoring an impaired body to a 'normal' level. The ideological role of doctors is, therefore, much more important than that of other professionals.

Until the sixties, almost all doctors in India belonged to the classical middle-class — owning and controlling their instruments (stethoscope, syringes... etc.) and conditions of production and not employing wage labour but basically living off one's own labour. The wealth amassed by this section of the middle-class has been through a commercial exploitation of consumers (patients) through professional monopoly over and mystification of medical science and technology; and not through the exploitation of wage-labour. Even now majority of doctors in India belong to this category of classical middle-class. But since late fifties, more and more doctors are entering into employment with the Government. This social layer is a wage-earner; does not own the instrument and conditions of its labour and apparently is part of the white-collar working class. But on closer examination, it would be clear that this layer's role in the process of social production of medical services is different from that of the working-class and that it belongs to the new middle-class — a peculiar product of developed capitalist society.

New middle class

The category — "new middle class" has been clearly formulated, developed in recent marxist literature. (For example, Carchedior, better, E. Wright) Briefly, the new middle class is a product of developed capitalism wherein a social layer occupies a position midway between the capitalist class and the working class by partly doing functions both of the capitalist class and of the working class. The "function of the collective worker" is geared to the production of use-values whereas that of capital is geared to the production of surplus value; (profit, rent, interest) and involves the work of supervision, surveilance. Wage earning doctors (medical officers) are on the one hand, part of the team of labourers consisting of nurses, midwives, technicians ...etc. doing materially useful work and like them not owning the instruments (medical equipment) and conditions (building and other infrastructure) of labour. On the other hand, they also perform the function of Capital, of supervising, extracting work from the paramedics. Their comparatively high salary, therefore, includes both a wage for the trained labour-power they sell and also part of the surplus value for performing the function of Capital. Along with foremen, executive engineers, head-clerks, junior officers and the ilk, departmental heads in educational institutions ..... this layer of doctors is part of the new middle

class. The junior doctors, a transitional phase in a doctor's life, is entrusted less with the function of Capital and hence is closer to the trained, skilled white collar working class The following analysis is applicable primarily to medical officers and only to a certain extent to the junior doctors.

This 'contradictory class location' of the Medical Officers would determine a great deal their contradictory role in the movement towards social revolution. As wage-earners, they are ready to unionise and fight for their demands, and this struggle demands an alliance with the rest of the working class against the state. But as officers, their interests demand a break from the subordinate working-class; a continuance of the hierarchy within the medical system.

There is a second couple of contradictory facets of medical officer's life — on the one hand, there is a need in this inhuman world of competition for amassing money, to earn more and more money through illegal, irrational private practice or through corruption to compete with and to be a part of the flock of the money-spinning community of fellow private practitioners. (This does not apply to the junior doctors. They do not do private practice.) On the other hand, as wage-earners, they need to accept limitations of a wage-earner, and are also expected to follow the ethics of a noble profession.

The third couple of contradictory aspects of this layer of wage-earning doctors is related to their ideological role. (In this respect, private practitioners also share this contradiction to a certain extent). On the one hand, the dominant ideology in the field of science and hence also in the field of medicine in capitalist society is that of technocratic scienticism i.e. of looking at health and disease as primarily a question of interplay of germs and chemicals amenable to drug-therapy. Added to this is a predominantly curative and individual-oriented as oppossed to community oriented approach to medical care. On the other hand, the very nature of the 'raw-material' on which the 'doctor-scientist' works demands a holistic, humane approach and an exposure (though in a limited and somewhat distorted fashion) to the science of community medicine; to the national health programmes, throws light on the limitations of a predominantly clinical orientation.

One more set of contradictory relations constitute the doctor's work — on the one hand, majority of doctors are drawn from upper-caste, urban background and are by and large male and hence are biased in favour of their own social background. On the other hand the science of medicine (though vitiated to a certain extent, by elitist, sexist bias) basically transcends these narrow barriers and exposes medicos to universal concepts devoid of narrow considerations.

What should be basis of doctor's organisation ?

The left has to grap these contradictions in order to determine its strategy of organising this layer of doctors. Secondly we should also be clear as to what kind of medical system we want to and can build in socialist India. Should we aim at a medical system which is in the process of freeing itself not only from commercialism of capitalism but also from other ills like hierarchy within medical system, mystification of medical knowledge and unnecessary glorification of medical profession, urbanism, elitism, sexism, allopathic chauvinism, scienticism... and so on? If yes, then in that case it s wrong to appeal medical officers mainly on the basis of their trade-union demands We should plainly point out their contradictory interests, and appeal them to choose, and stick to the positive, healthy, progressive aspects of their life-situation and organise a revolutionary union of doctors on the basis of this comprehensive plan. It is likely that only a small section of this new middle-class would come with us for this comprehensive revolutionary change in the medical system. That can not be helped. But to be sure, there is a definite objective basis for at least a small section to come over to the side of revolutionary programme.

Similarly, we need to concretely analyse the contradictory situation of other categories of doctors like private practitioners (classical upper middle class) junior doctors, consultants .. etc; and base our organizational strategy on that basis.

Unfortunately, today, there does not seem to be a well thought out strategy in organising doctors. On one had, medical Officers in Government service and resident doctors are being organized primarily on their trade-union demands. But things are not moving much beyond this narrow focus. At certain places, Left activists are the leading organizers of such organizations. They do get a few cadres for their party or group on the basis of Party's broader (non-medical) programme. Their medical programme however does not go much beyond asking for extension of medical services to all people. These Leftist organisers have not been able to foster a process of gathering medicos on the basis of a

comprehensive revolutionay medical programme which asks doctors to throw away their privileges as elite doctors in return for promise of decent, scientific, meaningful working life.

If there is a hope that doctors — a middle class — can be "neutralised" by catering to their trade union demands, then it is a misplaced hope; we must also understand that such a "neutralised' social layer would immediately spring into opposition if a thorough going change in medical system is proposed or is actually attempted. Radicalism of many leftist doctors is directed against injustice, irrationalities in the broader society; but has Penetrated only to a small extent in their own field, How can such a leadership foster a thorough-going change in the medical system ? A combination trade unionism in the medical field with broader left politics (but not inclusive of ills of the medical system enumerated above) will fall much short of revolutionary changes that can be made in the existing medical system. Some attempt in the right direction is being made in West Bengal during and after the state-wide strike in 1983. Apart from trade union demands they have asked for certain changes in the medical system, drug industry. It is difficult to judge from here, as to how much of their support for radical measures is a reflection of genuine change in the attitude of at least a sizeable number of doctors or only expresses the wish of a few leaders or worse, only a lip-service to radicalism in the medical field.

At the other end, many social activists criticise the doctors as if doctors ("barring a few exceptions") are basically anti-people. It is true that flourishing private practitioners, consultants, surgeons, hospital owners would, as a social layer be oppossed to a revolutionary change. But it is not realized by these critics that many wage-earning doctors have a lot of problems related to working conditions — they hardly have any say in the policy-decisions that affect their work, are constantly plagued by shortage of drug-supply and other facilities, have to cow down to the local bourgeois politicians, and at the same time are disliked, criticized by the people for 'poor service' for which many times they are not responsible. These woes, like those of workers in other public utility service, are genuine. Rather than ignoring their problems and be content only with criticizing their irrational, anti-people approach; why not analyse these problems and show them how they are problems of a system, how they can be eliminated only through a thoroughgoing revolutionary change in the medical system; (as part of a broad social revolution) and offer a programme, an organization which would help to do this? Many medical officers would not be interested in joining this organisation since they would not be prepared to leave many privileges that they currently enjoy. But why not build bridges across the valley that separates them from a people's front when there is some objective basis in their life situation? An approach which appeals doctors only on moralistic grounds is a mistaken one on many grounds and hence will not succeed in even rallying round even that small critical mass of doctors we need to forge in order to make any viable, sufficiently strong clamour for a revolutionary change in the medical sysrem.

In Defence of My Confusion

Imrana Quadeer

I read with interest Anant Phadke and Dhruv Mankad's defence of their editorial policy. My confusion only doubled when I realised that for them a policy is meant only to be stated and not implemented. Within a given policy framework, should not an article be edited or published with comments requesting the author to rewrite it? Instead of declaring it "disjointed" etc., etc. six months after it was published and that too because some one else pointed out a few contradictions!

The basis of my "confusion" as Anant and Dhruv understand it, stands out clearly from their letter itself. *While I think that not all health analysts have the required understanding of society at large (including myself) and they should therefore very consciously try to do so through the 'window of health"* (a point in my letter with which my critics agree but have preferred to ignore), *they choose to believe that "a rigorous, correct understanding of Health and Medicine would not be possible with a superficial understanding of society".* This may be the ultimate truth but given the status of "rigorous and correct understanding" of the health analysts I am not ready to take such an assumption for granted. While they presume that within their perspective any discussion on health and medicine "would necessarily be based on an understanding of society in general", I will plead that such over-confidence only leads one into complacency. In fact I would like to point out that unless and until all authors of SHR are aware of the fact that all their general theories will be tested in the field of health (and vice versa) by the circle of SHR readers and not in the circles of Social Scientist or EPW readers, the tendency to take general concepts as well as the readers for granted cannot be checked. It is true that SHR has not got involved into a discussion on the mode of production or the nature of the state but it is also true that it has neither helped us understand these concepts through health nor clearly demonstrated the need to grasp them for a better understanding of the health situation. Do we, then, mention these concepts only to establish our Marxist credentials ?

Essentially the difference of opinions between us boils down to perspectives. For Anant and Dhruv there are those clear headed few who know what is "correct" and therefore have a monopoly over marxist analysis of health. They will write about imperialism in health in SHR and if at all necessary, improve their understanding of imperialism in other intellectual circles.

For me SHR is the place where through health I must understand imperialism. I will therefore not let superficial handing of the concept pass unnoticed in SHR.

All this of course is not to deny my confusion but to say that till the clear headed ones pay some attention to its roots it is bound to grow and grow more.

One Sided Defence of Professional Interests

Anant Phadke

Sujit Das (SHR II : 2) starts from a correct observation that "...little study has been made to investigate analyse and understand the medical profession in the perspective of concrete reality." But his article does not help much in a critical analysis of doctors as a social layer but is an uncritical shame-faced defence of the interests of the doctors. Secondly, because of lack of clarity about the 'contradictory class location' of wage-earning doctors, he is unable to characterise them inspite of a long discussion (with many excursions into sub issues).

To begin with, a word about the title of the article. It reinforces the popular but mistaken notion of medical profession being only doctors, forgetting other medical professionals like nurses, social health workers and so on. The title reflects the perspective of the article of focussing on the interests of the doctors.

Das's defence of the interests of the doctors starts with his analysis of the general practitioners. It is true that this category of doctors is not involved in capitalist relations of 'production; but in petty commodity relations (not 'precapitalist mode of production') as part of a capitalist social formation. But it does not mean that he can not be an exploiter. Unlike retail store-keepers general practitioners have earned wealth quite out of proportion to their skill, knowledge and labour. Such doctors through their monopoly over medical knowledge and skills have earned money through commercial exploitation (price more than value). It is however, true that, as pointed out by Das, increased competition amongst doctors and the rise of state medical service is changing this picture especially in bigger towns and cities. Das is however, content with pointing out only the problems faced by GPS. This in itself does not tell us their possible role in social revolution and the attitude of marxists towards this layer. He does not mention their poor understanding of clinical or preventive medicine, their unnecessary use of injections to earn money, unnecessary use of drugs (rational or irrational combinations) many a times cursory, indifferent, attitude to patients, and so on. Likewise other contradictory aspects of their existence have to be brought out since it is these contradictions which tell us about the potentialities of change.

Confusion between two categories: Das clarifies that "the present discussion dwells largely on the doctor in-service among the practitioners of modern medicine". But doctors-in-service is not a homogenous category. Junior doctors are closer to the white collar working class, whereas the medical officers are part of the New Middle Class. Das is unable to see this distinction and therefo e discusses the 41 day strike by medical officers and engineers in West Bengal in 1974 and the movement of junior doctors in 1983 in the same breath, in the same section. Here again, he gives a one-sided picture which only defends the sectional interests of the doctors concerned. It does not give us an idea as to what would be the role of this layer of doctors in social revolution. The demands in the 1974-strike mentioned by Das were "exclusive executive power for the scientists, technologists and professionals in the scientific and technical departments of the state administration which were the preserve of the generalists and parity in pay-scale with the IAS". These are demands of a technocracy competing with administrative beauracracy! The most important issues in medical care like more resources for water and sanitation, proper training and importance to paramedics, rational drug policy, reorientation of medical education....these are not even mentioned by the 1974 strike. Then why does Das talk about the woes of these medical officers and give importance to this strike? This inability and unwillingness to focus on the contradictions of this section of doctors results in only defending the sectional interests of the New Middle Class. From the point of view of a social revolution, this is a fruitless exercise unless the most important issue of fundamental restructuring of health services are also taken up seriously (and not only for cosmetic purpose or for winning sympathy for a struggle basically aimed at sectional interests only).

In the junior doctors strike in 1983 however, the doctors' demand for proper facilities in the hospitals was also the people's need. Interests of doctors and the people coincided on one point. It is hoped that the movement of this section of the white collar working class would transcend more and more purely sectional interests. Only history can tell us whether the "basic people's demand" of the 1983 strike were genuinely raised or primarily to win public support for a movement for purely sectional interests. We would like to know from Das what efforts this organisation of junior doctors has made to pursue these people's demands during the last two years.

In this brief response, I would not go into Das's discussion on professionalism, role expetation, performance. One would only say that it suffers from the same one-sided, shamefaced defence of professional interests of doctors and their existing role.

Let us be clear about the role of the New Middle Class i.e medical officers (like most of the executive engineers, bank officers and others) in today's society, their contradictions and hence their role in social revolution. Even after a lengthy discussion, Das's article precisely fails in achieving this.

Forthcoming Issues

March 86	*Mental Health*
June 86	*Health care in post - capitalist societies*
Sept 86	*Primary Health Care*
Dec 86	*Environment*

Why don't you write for us ?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved.

Each issue of the journal will focus on one theme, but it will also carry (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

Our forthcoming issues will focus on : Mental Health, Health Care in Post-Capitalist Societies, Primary Health Care, and Environment.

If you wish to write on any of these issues do let us know immediately. We have to work three Months ahead of the date of publication which means that the issue on Mental Health is already being worked on. A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing style of reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. This need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be neatly typed in double, spacing, on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions **in a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are, working on issues of interest to you.

WORKING EDITORS

Please send me Socialist Health Review for one year (four issues). I am sending Rs. _____ as subscription and/or donation by Demand Draft/Cheque. (D D and cheque in favour of Socialist Health Review and for cheque add Rs. 5, if outside Bombay).

Name _____

THE MINER OF DHANBAD

A dawn rises in your dream,
but you go back to the longings of the coal.
Shovelling centuries back, you return
to the fiery springs
and the merry beasts of yore,
through the prehistoric dreams
of a sunlit village,
through the screaming skulls
of its grudging grandfathers

This earth lies unaware
of the acid and the dust
gathering the form of death
in your toil-torn lungs.
You shovel the coal, but
your naked children howl surprised
as the train passes by the hamlet

My brother, nameless, unknown,
Even you do not know
but for you the heart of Bihar,
its head raised like a seahorse's
stop to beat

Your mind is dry,
sterile like the River Damodar
in summer noons
The Buddha of Gaya ignores your prayers.

But tommorrow a sun will rise
from the flickering flame
of your charred heart,
you will find your forefather's dreams
in the single staring eye of the train, burning.

Mental Health and Society

Nowadays, men often feel that their private lives are a series of traps. They sense that within their everyday worlds, they cannot overcome their troubles, and in this feeling, they are often quite correct: what ordinary men are directly aware of and what they try to do are bound by the private orbits in which they live; their visions and their powers are limited to the close-up scenes of job, family, neighbourhood; in other milieux, they move vicariously and remain spectators. And the more aware they become, however vaguely, of ambitions and of threats which transcend their immediate locales, the more trapped they seem to feel—C.Wright Mills in "The Sociological Imagination."

THIS is the condition of modern man. In order to understand mental health and illness it is very important to know the concept or nature of man within a given social milieu; for on this depends the definition of what is mental health and illness, the normal and the pathological. The human situation or human existence in a social milieu thus becomes the key to understanding mental health.

It is not necessary to go into the various conceptions held historically but it should suffice to state that the definition of mental health in a society is intimately related to the concept of human in that society. These conceptions are the result of the relations of production prevailing within a given society. They have a direct bearing on the human situation and determine mental health of individuals as well as classes. Marx described this aptly in the 'German Ideology': "The production of ideas, of conceptions, of consciousness, is at first directly interwoven with the material activity and the material intercourse of men, the language of real life. Conceiving, thinking, the mental intercourse of men, appear at this stage as the direct afflux from their material behaviour. The same applies to mental production as expressed in the language of the politics, laws, morality, religion, metaphysics of a people. Men are the producers of their conceptions, ideas, etc. real, active men, as they are conditioned by the definite development of their productive forces and of the intercourse corresponding to these, upto its furthest forms. Consciousness can never be anything else than conscious existence, and the existence of men in their actual life-process." (Marx, 1956)

Thus, pathology stems from society itself and no amount of cure of an individual who manifests symptoms of being mentlaly ill, will provide a complete solution to this sickness. Mental helath is not a question "of the 'adjustment' of the individual to his society, but, on the contrary it (requires) the adjustment of society to the needs of man . . . whether or not the individual is healthy, is primarily not an individual matter but depends on the structure of his society. A healthy society furthers man's capacity to love his fellow men, to work creatively, to develop his reason and objectivity, to have a sense of self which is based on the experience of his own productive powers. An unhealthy society is one which creates mutual hostility, distrust, which transforms man into an instrument of use and exploitation for others, which deprives him of a sense of self, except inasmuch as he submits to others or becomes an automaton" (Fromm, 1956). It is therefore clear that the understanding of man's psyche "must be based on the analysis of man's needs stemming from the conditions of his existence" (ibid).

Historical Background

In the past mental illness was generally the equivalent of lunacy or madness but in post-industrial societies things are different. Understanding of mental health was earlier dichotomised into being mad or being sane. Now the situation has changed.

A change in the social formation cuts across the length and breadth of a social structure and leaves none untouched. The sphere of the human psyche too is affected. Traditional societies are close-knit and therefore have a greater capacity for absorption of distress, frustrations and conflicts that impinge upon individuals because of prevailing class-relations. Family, clan and community ties cushion members against them temporarily releasing them (individuals) from the traps of daily living.

With the industrial and French revolutions the old order received its death blow. Individuals, uprooted from their traditional ties, had to face new realities of changed production relations, but this time with little or no support from their family, clan or community. The new production relations under capitalism made alienation of man complete and mental health acquired additional dimensions. It was no longer confined to "madness" but smaller deviations from accepted norms became equally important, because a mass society that was emerging required stronger measures and mechanisms for social control if the status quo had to stay undisturbed.

The first break came during the "Paris Commune" when Philippe Pinel, a French physician, obtained permission of the commune to treat inmates of asylums with kindness and sympathy: instead of incurable lunatics they were now considered as "sick" persons who were in need of treatment rather than being evil and deserving punishment. Pinel's therapeutic intervention advocated a moral treatment—treating afflicted persons with care and concern and at the same time improving their environment; patients were taught the value of work, recreation, religion, social activities and self-control (Bockoven, 1963).

Thus for the first time the theory of unadjustment to society was put to practice and mental health henceforth became a matter of adjusting the unadjusted through a process of correction.

With further advancement of industrial society and strengthening of capitalism, issues of mental health were no longer confined to the lunatics, but increasingly neuroses began to acquire a central focus. This was thanks to the weakening of human ties and the process of alienation. Karl Marx described this as the negation of productivity in that man (the worker) can no longer "fulfill himself in his work but denies himself, has a feeling of misery rather than wellbeing, does not develop freely his mental and physical energies but is physically exhausted and mentally debased" (Marx, 1967). The man who has thus become subject to his alienated needs is "a mentally and physically dehumanized being . . . the self-conscious and self-acting commodity" (ibid).

Through Marx's writing it became clear that pathology resided not in the individual but within the social system itself. Mental illness originated in the pathological society and it was society that needed a total transformation; man's mental state depended upon the nature of the social system.

However, this explanation was set aside as it was a challenge that suggested the destruction of the existing system. Soon after Marx, Max Weber's verstehen approach came to the rescue of capitalism. Weber upturned Marx and provided a foundation for a new explanation to emerge about man's mentality. This new break was that by Sigmund Freud who directed attention to the intrapsychic life and emphasised the importance of the

unconscious. This psychology of the unconscious was indeed "revolutionary" and path-breaking because until Freud philosophers had always equated the mind with consciousness. Freud's now famous "ice-berg" theory revealed that "only a very small part of what is mental is conscious; the rest is unconscious made up of inadmissible and involuntary ideas which motivate behaviour" (Appignanesi and Zarate, 1979).

Sigmund Freud

"Where id was, there shall ego be" was Freud's way of describing mental health. Id is the unconscious, governed by the pleasure principle, and ego is the preconscious that emerges because of the reality principle. These ideas of the unconscious revolved around the oedipus complex which has generally acquired the expression 'father ... murder, mother ... incest'." In Freudism 'libido' plays the part of the mythical 'caloric' of eighteenth century health mechanics, or of the 'gravity' of Newtonian physics (Caudwell, 1971).

As a consequence, Freud's obsession with sexuality prevented him from using to advantage the contributions of Marx to the understanding of human behaviour.

Freud's sexual determinism is unrealistic. A child's desire for his mother's breast and subsequently for her love is not an incestuous response but that of hunger and emotional support; for the child it is the mother who provides social, economic and emotional security. Nor does the child see the father as a rival or, in his unconscious, desire to murder him. The father's role as a patriarch bestowed by society is interpreted by the child as a stranglehold on his freedom, creativity and object of security (the mother), and therefore in his unconscious he seeks to challenge it. A review of anthroplogical studies of matriarchal societies may indicate possibilities to further substantiate and support this critique of Freud's conception.

Freud's insight of the human psyche was based on an understanding of the individual, and as a consequence his interpretations of mental manifestations suffered severely. He did not see the individual's psyche in the context of the social milieu and therefore got trapped in the confines of the libido instinct.

Caudwell (1971) writes: "We must establish sociology (Marxist) before we can establish psychology, just as we must establish the laws of time and space before we can treat satisfactorily of a single particle . . ." This Freud has failed to see. To him all mental phenomena are simply the interaction and mutual distortion of the instincts, of which culture and social organisations are a projection, and yet this social environment, produced by the instincts, is just what tortures and inhibits the instincts.

However, Freud's influence on the various disciplines of the human psyche is still very substantial. Freud's contributions have greatly been responsible for the extensive attention that mental health receives, especially in western countries. It was largely due to the emergence of Freudian psychoanalysis that the mental health movement became popular in the USA. The professions of psychiatry and psychoanalysis subsequently acquired a new importance in the field of medicine—they became big business; a new technology developed around them—psychotropic drugs, psychosurgery, electrotherapy and the like. Until the late sixties, this individualistic approach to mental illness remained predominant.

Community Mental Health

At the turn of the seventies, by when the futility of the individualist approach was proved beyond doubt, things began to change. The community basis of mental health was recognised in the USA, but still the problem continued to be seen as one of adjustment and unadjustment to society. The difference was that it was not the individual that required to be adjusted, but the entire community in which he lived. Thus, if the mentally disturbed person came from a ghetto then psychiatric social workers and other paramedics were to be used for resocialisation of the immediate community of the mentally ill person; these paramedic workers thus became a new arsenal in the forces of social control.

It would be of interest to list out the characteristics of this community mental health movement (Bloom, 1973): a) emphasis on practice within the community rather than in institutional settings such as mental hospitals; b) effort to provide services and programmes directed at the total community rather than individual patients; c) prevention services given higher priority than therapeutic services; d) clinician offering indirect services—consultation, mental health education, training of community care givers (teachers, clergy, public health nurses, etc.)—rather than working directly with patients, thus reaching larger number of persons; e) innovative clinical strategies developed that more promptly meet the mental health needs of larger number of people (eg: crisis intervention) than was possible before; f) more rational basis for developing specific programmes, based upon a demographic analysis of the community being served, its unmet mental health needs, identification of those persons who are at special high risk for developing disordered behaviour; g) use of new personnel—para-professionals—to supplement services delivered by psychiatry, clinical psychology, psychiatric social work and psychiatric nursing; h) committment to "community control" dealing with community representatives in establishing programmes; and i) identifying sources of stress within the community and not simply within a sick person.

From the above listing it becomes clear that the community mental health movement is no different from the community health movement which aimed at developing resources in a decentralized manner (at the community level) so that through a new category of resource persons (such as paramedics, "voluntary" agencies or NGOs, etc.) the ruling class could strengthen mechanisms of social control, making them appear as self (or community) regulatory and democratic; thus, preserving the status quo. This fits in with the 'circulation of elite' framework of Vilfred Pareto which is regarded as a weapon of the ruling class (elites) to protect its own decadence "by introducing the idea of new 'social forces' among the masses" (Bottomore, 1966).

Dimensions of Mental Health

In spite of the understanding that the social structure of capitalism is in itself responsible for mental illness an overwhelming proportion of psychiatrists and psychoanalysts continue to treat mental illness as a primarily biological and behavioural problem. Therapeutic systems that have been evolved in recent years are therefore based on these assumptions and hence inadequate.

The problem of mental health, though having its own peculiarities, is no different from that of health in general or other social problems such as poverty, communalism, racism, sexism, arms race, etc. All these problems, both under capitalism and totalitarian socialism, are dealt with by society from the perspective of commanding social control. In the case of mental illness those afflicted, i.e. those not conforming to the norm, are subjected to degradation, segregation and isolation (in asylums) and more recently to incarceration, surgery, various chemical treatment procedures and inhuman psychological therapies, all directed towards driving home the point (to the patient as well as the population at large) that norms of society are sacred and unquestionable and must be followed at all cost.

Those whose behaviour is not accounted for by the rule-following model face not only the above stated consequences but are also labelled (eg: schizophrenic, hysterical, manic-depressive, catatonic) and stigmatised.

Erving Goffman calls this process 'mortification'. He writes (Goffman, 1984): "On admission to an asylum the 'patient' is stripped of his identity and any social support he enjoys. He begins with a series of abasements, degradations, humiliations and profanations of self. His self is systematically, if often unintentionally, mortified. The staff employs procedures on admission that complete this process of mortification—taking of life history, photographing, weighing, fingerprinting, assigning numbers, searching, listing personal possessions for storage, undressing, bathing, disinfecting, haircutting, issuing institutional clothing, instructing as to rules, and assigning to quarters."

Mental asylums are thus not very different from penal institutions having as their main function the correction of unadjusted behaviour; a process one may call resocialisation, which at times may go to the extent of disculturation (rendering temporary incapacity of managing normal day to day life processes when one gets out of the asylum).

It has been proved adequately that the therapeutic effects of currently practised psychotherapy "are small or non-existent and do not in any demonstrable way increase the rate of recovery over that of a comparable group which receives no treatment at all" (Eysenck, 1965). Thus, concludes John Ehrenreich that psychiatry "is the branch of medicine which openly specialises in the social control of deviant behaviour" (Ehrenreich, 1978); and Thomas Szasz adds, "therapeutic interventions have two faces; one is to heal the sick, the other is to control the wicked ... contemporary medical practices—in all countries regardless of their political make-up—often consist of complicated combinations of treatment and social control ... psychiatric diagnoses are stigmatizing labels, phrased to resemble medical diagnoses and applied to persons whose behaviour annoys or offends others" (Szasz, 1974).

Beyond the asylums, in daily life, such interventions are increasingly manifesting themselves, becauses problems which are essentially social are being further appropriated by the medical professions.

Mental illness is today generally classified into two categories—*psychoses* and *neuroses*. "What most patients of the first group suffer from is anxiety or depression, which if it exists in a mild form, may only be neurosis. When it reaches a severe stage, the person becomes totally abnormal. the opposite extreme of depression is excitement or elation; when depression and elation are manifest in a cycle, it is known as manic-depressive psychosis .. (Among neuroses) the commonest is the anxiety neurosis, followed by obsessional neurosis, the compulsive urge to wash your hands, a fetish for cleanliness, an abnormal concern about pollution. All the phobias too come under this classification" (Chakraborty, 1985).

In a survey conducted recently in Greater Calcutta it was found that 140 per 1000 persons suffer from some mental illness or the other. Neuroses affect one in ten of the population. The psychotic group is smaller, 16 per 1000 persons and half of these are acute cases, incapable of functioning socially; this is a very low figure in the international context, surprisingly so in a city like Calcutta where one expects more psychotic problems since the major factor, stress, is so overwhelmingly present (ibid).

Poverty and inhuman living conditions, especially in the third world, play a significant role in determining mental health. The working classes trapped in unfavourable work situations and unhygienic conditions are probably the worst off due to their alienated state. These cases of mental disturbances may not be recorded as neuroses or psychoses but the fact remains that their mental health is poor because even obtaining two square meals is a struggle: which means a lot of insecurity and mental trauma.

Minority communities and underprivileged castes in India, blacks in South Africa and a few western countries also live under a fear psychoses that adversely affects their mental well-being. Women as a group have historically faced and continue to experience mental trauma as a consequence of their placement in a patriarchal society. Males have throughout history enjoyed the privilege of double values whereas females have always been suppressed, their entire life-cycle being explained in terms of their uterus and sexual function, especially from the medical perspective (Ehrenreich and English, 1978). This results in differences of interpretation of the same qualities held by men and women. This is explained very well in a paper by Vibha Parthasarathi (quoted by Kalpana Sharma in the Indian Express Magazine, 27th October 1985). She writes that the quality of being "open" is interpreted as "flexible" for men and "fickle" for women; the quality of being "forthright" is interpreted as "frank" in the case of men and "rude" in women; "resoluteness" as "firm" for men and "rigid" for women; "unflinching" as "strong-willed" for men and "stubborn" for women; and so on. As a consequence these biased interpretations are in a large measure responsible for the neuroses or psychoses in women.

The modern world of advertising in capitalist societies and propaganda under both political systems promote values of the status quo, numbing creativity of the human species, inculcating a consumerism that drives man into becoming an automaton; he either becomes obsessed with the advertised or propagated norms and is labelled as an obedient or good citizen or he rejects these norms and is classified as a deviant, and if the deviance goes beyond the acceptable limits the person is labelled mentally ill, thus becoming a prey to the therapies of psychiatrists and psychoanalysts.

And finally patriarchy, which manifests itself through exploitative production relations, also contributes to mental pathology. Patriarchy, besides promoting sexism and suppressing women, promotes the idolatory of the clan, the race and the nation; it is in Freudian terms an incestuous fixation. It is manifested in our times in totalitarian regimes, bureaucratisation and monopoly control of productive forces, among other things. Fromm puts this point forcefully when he points out that "nationalism is our form of incest, is our idolatory, is our insanity; 'patriotism' is its cult" (Fromm, 1956). He furthers this argument by indicating the similarities between capitalism and totalitarian socialism. "Both systems are based on industrialisation, their goal is ever-increasing economic efficiency and wealth. They are societies run by a managerial class, and by professional politicians. They both are thoroughly materialistic in their outlook regardless of Christian ideology in the west and secular messianism in the east. They organise man in a centralised system, in large factories, political mass parties. Everybody is a cog in the machine, and has to function smoothly. In the west, this is achieved by methods of psychological conditioning, mass suggestions, monetary rewards. In the east by all this, plus the use of terror (or course, the west also uses terror—the 'spectre of Communism'). It is to be assumed that the more the Soviet system develops economically, the less severely will it have to exploit the majority of the population, hence the more can terror be replaced by methods of psychological manipulation. The west develops rapidly in the direction of Huxley's 'Brave New World', the east is today Orwell's '1984'. But both systems tend to converge" (ibid).

Conclusions

Medicalisation of human mental situation, the social control that goes with it, the alienation that class-relations generate

and the general drugging of the human mind through the modern information systems have made an obedient cog of him/her. Then, if the currently prevailing social formations are largely responsible for mental distress and frustrations, what does the common man look towards?

It is a difficult question to answer. Psychoanalysis, like psychiatry, has failed in its purpose. In the west, as well as east bloc nations, the former has become only an appendage of the latter—which is highly medicalised. In the underdeveloped countries, especially of Asia and Africa, both psychoanalysis and psychiatry have not found any significant roots, but in most of these countries traditional ties are still strong enough to provide comfort from the trappings of the social system.

Isn't this itself an indicator that a community-life that is *free* from exploitative class relations, patriarchy and a centralised and bureaucratised social control system will lead us towards a mentally and socially healthier life?

It has indeed been a difficult theme to compile. All the articles, except David Ingleby's which has been reproduced from a collection of the Radical Science Collective, are on psychiatry. We begin with Dilip Joshi's Psychiatry: State of the Art, which takes a look at present day psychiatry and its medicalisation.

Next we have Annie George's article which reviews the training programmes for medical and psychiatric social work and the role social workers play in psychotherapy. Psychoanalysis, that is extremely popular in west, is of little consequence (in practice) in our country—we present Ingleby's article that deals with ambivalence of psychoanalysis. This is followed by a short piece on a psychiatrist, Anand Nadkarni's experience in becoming one. We have two review articles, one on psychosurgery by Bindu Desai and the other on gender differences by Nalini. In addition we have a long non-theme article on experiences of a participatory research project on women and health by Gabriele Dietrich.

LOCOST

Research Proposals Invited

LOCOST is a non profit trust that seeks to promote the rational use of medicines. We also supply quality drugs to those working with rural/urban poor.

LOCOST offers support for research in the following areas: (1) Review of academic literature of specific drug categories like analgesics, antispasmodics, haematinics, etc. and/or of controversial drugs like analgin, etc. (2) Identification of information gaps in drug usage, ADR reporting, and designing and implementing study to fill up gaps. (3) Review of contents, sales, prices, market share, etc. of top selling allopathic and traditional medicines, fixed dose combinations, and over-the-counter products. (4) Review of promotional literature of top selling formulations and companies. (5) Production/distribution bottlenecks of some essential drugs like Vit. A, Rifampicin, INH, etc. (6) Price/sales trends of essential drugs. (7) Social cost benefit analysis. (8) Prescription pattern studies and prescription guidance. (9) Perceptions and responses related to communication processes and aids in drug selling and in drug therapy.

LOCOST's priorities are towards rural poor and urban poor. Our budget is modest. Well designed short term (one month to six months) research proposals, with concrete output on which action can be taken are welcomed. Write to: **LOCOST, GPO BOX 134, BARODA 390 001.**

Psychiatry: State of the Art

dilip joshi

Psychiatry, over the years, has been thoroughly medicalised—it views mental illness as a purely biological problem. The author presents a critique of the prevailing worldview of psychiatry and its practice. He argues in favour of a discounted alliance between psychiatry and medicine so that a more human psychiatry may be evolved.

MENTAL illness seems to be the major problem of our time. In the United States doctors write 200 million prescriptions each year for psychoactive drugs. Half to one million people are treated for 'schizophrenia'. In Britain, on the other hand, 25 per cent of all hospital beds are occupied by the mentally ill. One in nine men and one in six women can be expected to enter a mental institution in their lifetime (Ingleby 1980).

Psychotherapy—Current Perspectives, a book written by a group of psychotherapists, reveals an astounding scenario. The child consults a school-counsellor, mother of the child attends consciousness-raising groups for women, father attends 'T' sessions at factory and the grand-parents participate in a workshop conducted by a professional on 'pains of ageing'. Psychiatry today permeates and encompasses all significant events in human life. (Cottle and Whitten, 1980). On the other hand within psychiatry there is no consensus about:
(a) What are mental illnesses? (b) Who should treat them? (c) What are the means (how to?) and what are the ends? (What is cure?)

We have a vast amount of literature on mental illness compared to our inadequate understanding about it. Is there something fundamentally wrong? This article takes up these issues and examines them critically.

Mental Illness Not a Disease of the Body (Brain)

One is often told during training that 'schizophrenia' is a disease of body (brain) like diabetes, hypertension (high blood pressure). One is also told that we are ignorant about the cause of 'schizophrenia' but is it also not true of a bodily disease like cancer? 'Schizophrenia' is presented as a disease of body (brain) with a fixed cause which is being found out. One is reassured that with the advance in medical technology, psychiatry will be able to solve the riddle of 'schizophrenia'.

The present day trend in psychiatry is towards explaining mental illnesses as disorders of brain chemistry. It is speculated that tomorrow we will possess such powerful drugs to cure mental illnesses that psychiatry will not exist as a separate discipline but will be incorporated in clinical medicine and even general practitioners will be able to tackle these problems.

But let us look for evidence. Seymour S. Kety has done the most extensive work on 'Bio-chemistry of Schizophrenia'. He says that his work is inconclusive about 'schizophrenia' being a bodily illness (Avieti).

One does not deny that physical illnesses and drug-induced states produce a picture resembling mental illness. But Seiger, Osmond and Mann (1969) disagree about closeness of drug induced states with real illness. Dr. Joseph Berke argues that in 'schizophrenia' hallucinations are mainly auditory. While under the influence of psychedelic drugs people rarely have hallucinations of any kind. Most of the experiences of false perceptions (illusions) are visual in nature (Berke).

One of the main theories about 'schizophrenia' is the dopamine theory. It states that the specific behavioural symptoms are produced by excess of dopamine in the brain (Kaplan and Saddock, 1980). If one finds that an abnormal behaviour (inability to work consistently, inability to relate to people, etc.) or an abnormal experience (inability to experience pleasure, feeling that whole world is against you, etc.) is accompanied by a change in body chemistry (excess of dopamine in brain) one cannot conclude that excess of dopamine is the cause of this behaviour or experience because:
(a) One considers excess of dopamine as abnormal only because one took the behaviour or experience as abnormal in the first place.
(b) One is correlating an entity in the natural domain (excess of dopamine) with a phenomenon in experimental domain which one cannot correlate scientifically.
(c) The excess of dopamine can be subsequent to the experience.

Let us further clarify the difference between a physical illness and a mental illness by taking the example of hypertension and 'schizophrenia'.

When as a doctor I find that the blood pressure of the person sitting next to me is more than 120 over 80 millimeters of mercury, I tell him that he is suffering from hypertension. Whatever my values, my beliefs they do not influence what I see or observe, hypertension remaining a similar entity all over the world.

On the other hand when a psychiatrist makes a diagnosis of 'schizophrenia' he is judging the behaviour or experience of the person sitting next to him according to certain prevalent (cultural) beliefs about human nature and what he sees is influenced by what he believes.

The findings of United States-United Kingdom Joint Schizophrenia project reveal that American psychiatrists tend to diagnose 'schizophrenia' much more frequently than their British counterparts. For a similar case an American psychiatrist will diagnose the person as 'schizophrenic' while the Britisher would not (ibid).

Objectivity of Diagnosis in Psychiatry

"The diagnosis of schizophrenia should rest on whether a normal person understands the person concerned's behaviour"—Manfred Bleuler, a leading psychiatrist (Laing, 1982).

So how are psychiatrists different from lay people? A lay person also understands that a person is behaving in an unorthodox way, the psychiatrists call it 'schizophrenia'. But what have they gained in the process? Has calling the person 'schizophrenic' rendered his situation, his response, more intelligible? No. One feels that the exercise of diagnosis is for screening normal, good, conforming behaviour or experience from an abnormal, bad, nonconforming one; rather than to really understand the *genesis* of that behaviour or experience. This distinction is made by the psychiatrist on the basis of certain prevalent beliefs about human nature and hence in the psychiatric interview a fact never remains a fact, it already becomes an interpretation, a value judgement (Goldmann).

A-priori Assumptions About Human Nature in Psychiatry

These assumptions are based on an image of the human being as a sociable, non-violent, hardworking, rationally profit making organism. These assumptions are revealed when one sits in the psychiatry out-patient department and makes a list of most

frequently asked questions. These questions are:
(a) whether the person works regularly? (b) whether he/she mixes with others? (c) if in business, is there adequate profit making? (d) whether he/she is violent towards self or others? (Thines)

This human nature is supposed to be all pervasive and universal, according to the psychiatrist. But let us look around, let us go into the past to find out whether this is true.

Can one say that human nature is essentially peace loving, non-violent when one looks back at Nazi concentration camps, the bombing of Hiroshima and Nagasaki? Where is the sociable human nature when two communities exist side by side in the world with evergrowing paranoia about each other?

Can one find a hardworking human being amongst those few who rule the world today and enjoy at the cost of toiling masses? Isn't the wealth of many European countries smeared with sweat and blood of the colonised people?

Man is yet to be born. On the totality of images that we create by our praxis in the world depends the future image of man. As of today, this is a period of inhuman exploitation of men and women and a narrative of violence to maintain and perpetuate that oppression. It is surprising then that those who are most frequently diagnosed as mentally ill belong to the category of defenceless (poor, children, women, aged) or those whom the middle-class, superior caste/race psychiatrist cannot understand—the ethnic minorities, people who live on fringes of cities. Half a million children in the United States receive treatment with powerful psychoactive drugs for being 'hyperkinetic' (Ingleby, 1980). The incidence of 'schizophrenia' is more in the lower socio-economic strata (Lidz).

Practice of Psychiatry

"Cure is accomplished when the former person becomes an obedient robot moving around either in the chronic backwards of mental institution or without any human sense in the outside society . . ." (Cooper, 1974).

Antonin Artaud, a great poet, wrote with anguish after being given electroshocks in a hospital at Rodez "I died at Rodez under electroshocks. I say dead, legally and medically dead" (Greene).

Ernst Hemingway describing his experience of shocks to his friend said, "it was a brilliant cure, but we lost the patient. It killed both my soul as well as my mind." He committed suicide a few months later (Madness Network News, Fall 1984). A violonist who was given shocks for depression in a Glasgow hospital, could not later on give her performance as she lost her violin repertoire (Laing, 1976). Most of the groups working for a ban on electroshocks in different countries of the world claim that not only do shocks cause memory loss, disorientation wild excitement or terror, but shocks can also kill. Shock is not only a procedure wherein electric current is passed through the brain of a person but also the dehumanising ritual of being forcibly held by people, being forced to lie down, etc. which a person has to go through. Why are people not told about the after-effects of shocks? Why are they not told about the procedure? I am sure if the procedure is described to the person, he will never like to undergo such a dehumanizing experience. Shocks are either mystified—'Its only an injection', 'You will be cured', or they are offered as an alternative to long term hospitalisation. In a similar situation a group of prisoners agreed to participate in an experiment which they knew would damage their health, so as to get their prison stay reduced.

Dr Caligari's *Psychiatric Drugs*, a book published from Berkeley, informs us that psychiatric pills neither tranquillise nor elevate our mood, they actually deaden our feelings and our bodies. Drugs like thovagine, steliazine, nlehavil, haldot (all anti-

Towards a Human Psychiatry

Present day psychiatry considers the person as a passive object, who reacts in a determinate way to his situation. It shows complete disregard for human subjectivity. Between our interiorisation of exteriority (family, class experience) and our re-exteriorisation of this interiority, i.e. in the passage from exteriority to exteriority (objective to objective) there is a moment of human subjectivity. We do not necessarily reproduce in the same exact fashion the exteriority which we interiorise. In other words we can always make something of what is made of us. This is the realm of human freedom. This is ignored in the constitution of the person as passive object.

Economic and Political Weekly

A journal of current affairs, economics and other social sciences

Every week it brings you incisive and independent comments and reports on current problems plus a number of well-researched, scholarly articles on all aspects of social science including health and medicine, environment, science and technology, etc. Some recent articles:

Mortality Toll of Cities—Emerging Pattern of Disease in Bombay: Radhika Ramsubban and Nigel Crook
Famine, Epidemics and Mortality in India—A Reappraisal of the Demographic Crisis of 1876-78: Ronald Lardinois
Malnutrition of Rural Children and Sex Bias: Amartya Sen and Sunil Sengupta
Family Planning and the Emergency—An Unanticipated Consequence: Alaka M Basu
Ecological Crisis and Ecological Movements: A Bourgeois Deviation?: Ramachandra Guha
Environmental Conflict and Public Interest Science: Vandana Shiva and J Bandhyopadhyay
Geography of Secular Change in Sex Ratio in 1981: Ilina Sen
Occupational Health Hazards at Indian Rare Earths Plant: T V Padmanabhan

Inland Subscription Rates

Institutions/Companies One year Rs 250, Two years Rs 475, Three years Rs 700
Individuals Only One year Rs 200, Two years Rs 375, Three years Rs 550
Concessional Rates (One year): Students Rs 100; Teachers and Researchers Rs 150
(Please enclose certificate from relevant academic institution)
[All remittances to **Economic and Political Weekly**. Payment by bank draft or money order preferred. Please add Rs 14 to outstation cheques for collection charges]

A cyclostyled list of selected articles in EPW on health and related subjects is available on request.

psychotics), tofanil, elavil (antidepressants) have a damaging effect on the brain.

Tandive dyskinesia is a syndrome charecterised by involuntary movements of tongue, face, neck, developing after long term antipsychotic medication. It is difficult to cure. The addiction potential of diazepam (valium, calmpose) is also mentioned in the book. A separate chapter instructs the readers on how to safely and gradually withdraw from psychiatric pills. But people coming to psychiatry departments are hardly told about the after effects of pills. Why?

Critique of Medicalised Psychiatry

In his postscript to 'Discussion of Lay Analysis' Sigmund Freud emphasised that psychoanalysis is not a branch of medicine but comes under the head of psychology and the training for psychoanalysis differs from that imparted to physicians. More important than whether the trainee is a medical graduate or not, is the specialised training for psychoanalysis. He also stressed that the trainee will have not only to study psychology but also sociology, history of civilisation, Darwin's theory of evolution, etc. But has psychiatry paid any heed to Freud's advice? No. Even to pay heed to it, it will have to read, remember his work and not repress it.

Today the alliance between psychiatry and medicine is complete with incorporation of psychiatry into general hospitals. Those who train in psychiatry are medical graduates who take up psychiatry as a postgraduate discipline, while in his days Freud defended 'lay analysis' (McGuire).

The present day psychiatry is medicalised psychiatry with its belief that mental illnesses are due to disorders of brain chemistry, with its emphasis on diagnosis and classification (labelling) and its promise of instant cures with pills and shocks.

By proclaiming that mental illness is a physical illness, it situates the problem inter-individually, allowing family and society to wash its hands of the person and hence it remains essentially status-quoist. By giving more emphasis on diagnosis and classification than understanding, intelligibility, which requires empathy, it is basically screening people who cannot fulfil the expectations the society has of them, on behalf of the ruling class.

By its reliance on pills and shocks it ends up by medicalising human problems and hence psychiatric therapy has on the contrary damaging effects.

For lay people psychiatrists wearing white coats, dispensing medicines appear scientific, objective. But if there is no consensus on fundamental issues in psychiatry, if there is more emphasis on labelling than understanding, and if the therapy is arbitrary and damaging, any amount of scientificity that psychiatry will try to bring in from outside, from its white coats, its pills, its sophisticated research on the body of 'schizophrenics', its alliance with medicine, will be futile.

On the other hand the present day psychiatry believes that the psychiatrist is a passive observer. He does not influence the situation, he does not see what he wants to see. By constituting the person as an object, an ensemble of physico-chemical entities, which is only worth effort of labelling and classifying, the psychiatrist remains totally external to the lived experience of mental illness.

Mental illness is nothing but a response of the person to his situation. We will be able to comprehend it only when we grasp the situation to which it is the response. It is also essential to understand the lived experience of mental illness with the help of mediations like family and class.

Instead of being a discipline which of necessity must give respect to the dignity and freedom of the individual, present day psychiatry is repressive. It should be our common endeavour to reinstate this respect for human dignity and freedom in psychiatry so that it will really be a human psychiatry.

Socialist Health Review

will now be

RADICAL JOURNAL OF HEALTH

We regret to announce that despite all our efforts we have not been able to register the publication under the name Socialist Health Review. We have been allowed the use of **RADICAL JOURNAL OF HEALTH**, which incidentally was our last choice! The issue of June 1986, Vol III number 1 of SHR will appear as **RADICAL JOURNAL OF HEALTH**. Please note that the objectives and purpose of the journal and therefore the choice of content, will remain the same.

The Helping Profession: Is It Really Helpful?

annie george

The role of medical and psychiatric social work in dealing with the mentally ill has been considerably enhanced due to the community mental health movement. What is the role of the social worker? How adequately are they trained for handling their task? In this article the author, herself a trained social worker, addresses these questions and presents a critique of psychiatric social work programmes as they exist today in the context of the Indian situation.

IT is generally accepted today that the causative factors for mental ill health are multifarious and interlinked and so their handling on many fronts—curative, preventive and promotive—is done by a multidisciplinary team. Traditionally, and till today, mental ill health has been seen as an illness in a clinical sense, and so the doctor is the person with whom the mentally ill person comes in contact for treatment. But increasingly, and cardinally, through the influence of developments in this field in the west, other professions have been roped into the field of mental health. Psychiatric social work is one such profession.

Who is helped through the intervention of social work, the "helping" profession, in the field of mental health? What were the roles assigned to it historically, and how have they changed to fit the mental health situation in India today?

Evolution and Contributions of Psychiatric Social Work

The concept of what constitutes mental health and ill health has always varied, and with it has changed the role of the social worker. The western practice upto late 19th century was to segregate the mentally ill persons in asylums, away from the mainstream of society. Since such persons were considered incurable, no psychiatric attention was given to them; social work intervention was also non-existent. By the end of the 19th century the understanding of mental illness in western society had changed considerably: mentally ill persons were now considered "sick" and various physical and psychological therapies were tried on them. The underlying assumption of such an approach was that people became mentally ill because of their inability to adjust to the pace and demand of urban industrialised life. Various theories citing psychological factors intrinsic in the "sick" individuals were put forward as the cause of their maladjustment; but whatever the understanding and the line of treatment, the end goal of the process was definite—the mentally ill person had to be treated such that he/she would be able to adjust back to society.

In the practical application of this conceptual framework there was tremendous scope for social work. Medical and psychiatric social work emerged in the USA and Great Britain in late 19th century because doctors there felt the need for a person who would supplement the service of medical care provided through hospitals. Social workers were used by them to get a more complete picture of the patient's background by providing psycho-social data about the patient. In India psychiatric social work started because Indian doctors had gone abroad and had seen psychiatric social workers and wanted them to act as "acolyte" to the high priest, the doctor. (Marulasiddaiah and Sharriff, 1981).

Right through the sixties, in the west, the treatment of the mentally ill was predominantly individualistic, institution-based and curative; this is the approach which is prevalent in India today. The role of the social worker was to understand the behaviour of people when they are (mentally) ill, the potentialities within individuals and their families, the resources in the community, the environmental effects associated with the disease, creation of insight into their problems, to bring out a social diagnosis and to suggest means of treatment together with physical and other psychological methods which would help them *revive their strengths and become active citizens* (emphasis mine) (Marulasiddaiah and Sharriff, 1981). In other words the social worker used all possible means and resources to help the person adjust to the very conditions which caused the problem. Through experience, social workers realised that other social groups to which the mentally ill person belonged, like the family and the work group, could also be used in the process of getting the person readjusted. Thus emerged treatment methods like family centered therapy and milieu therapy.

By the seventies there was a growing disillusionment with the person-centered, curative approach. Individual care in helping the mentally ill person to adjust was time consuming, expensive, and its results were seen only after a long period of intervention. Community based mental health services were seen as an alternative. In this approach like the earlier individual-centered one, the basic understanding of mental health had not changed; the contributions of social conditions—growing alienation, pressures of urban competitive life, erosion of traditional community support systems—to mental ill health were not acknowledged. Mentally ill persons, those who deviated from the norms determined by society, still had to be adjusted to fit into that society. The difference was that the adjustment would start with the community, would focus on preventive measures and would reach out to more people by training people from the community as frontline mental health workers. For the social worker the essential difference was that instead of treating the individual as an unit of work, the community became the work unit. Her major role would now be to provide psycho-social data about the community, and to plan programmes to prevent mental illness, programmes which includes recreation facilities for adolescents, family life education, and so on. Since the community health movement has not gained much ground in India, there are not many community based mental health programmes. Activities like organised recreation activities for children, fun fairs and sports days which are organised by social work agencies for disadvantaged groups usually go under the garb of community mental health programmes. These programmes may temporarily divert the attention of the people from their problems of daily living but they do nothing to alleviate them.

Though the role of the psychiatric social worker has changed through various approaches to the treatment of mental ill health, her contribution to society has remained the same: to identify mentally ill persons, to treat them in a congenial manner through social work techniques, to resocialise the person to the requirements of society, and if such resocialisation is not possible, to segregate the person from society so that other normal people are not disturbed in their daily functioning. In fact, the social control aspects of the job generally remain in the background, and what emerges for the mentally ill person and the public at large to behold is a gentle, caring woman (psychiatric social worker) whose entire function is to be at their service and to look after their problems. Most medical and psychiatric social workers are women; other specialisations of social work like community development or criminology are considered the male domain. Medical and psychiatric social work

is probably seen by most people as an extension of the traditional role assigned to women as the caretakers of the sick and helpless members of the family. Moreover, traditionally, the woman bears the responsibility of socialising the child and psychiatric social workers, as an extension of this traditional role, resocialise the mentally ill person who has lost the social skills which are necessary to survive in an industrial, competitive world. Thus through their legitimately assigned task of labelling (diagnosis), treating and/or confining persons with deviant behaviour, the psychiatric social workers perform a subtle and sophisticated form of social control. Her efforts to identify and change the stress inducing elements inherent in the way society has been organised are negligible. The present day social work education programmes are partly responsible for this state of affairs.

Psychiatric Social Work Training Programmes

Entrants to the field of psychiatric social work are trained for the profession through a two year course, generally conducted at the post-graduate level. Some schools of social work in India offer specialised training in medical/psychiatric social work. At such schools, in the first year students are taught basic courses in the methods of social work, human behaviour, man and society, and some electives. It is in the second year generally that courses related to the specialisation are taught. These usually include courses on psychiatric information for social workers, courses on methods of social work used by psychiatric social workers—mainly casework, or working with an individual and his family—and concepts from different schools of thought, like Freud, Rank and Parsons which have practical use in casework. Much of the theoretical base and action of medical and psychiatric social work is derived from Talcott Parsons' model of the sick role, in which, sociologically, illness was seen as a form of social deviance where an individual adopts a specific role. The sick role was characterised by the patient's temporary exemption from social responsibilities, and freedom from blame for being sick. However, since the role was considered undesirable and socially not approved, the sick person was expected to seek professional help to get well, and to comply with the treatment prescribed by the medical personnel. Though Parsons' model of the sick role provides the basis of work for the psychiatric social worker, in terms of treating mentally ill persons and getting them back to perform their socially defined roles, it also is a legitimisation of the power of mental health personnel over mentally ill persons who have to comply with the treatment of the professionals in order to have the label of social deviant removed. In the theoretical part of the training most emphasis is given to casework than on any other method of social work. In casework the focus of content is on various theories which explain human behaviour and which therefore help the psychiatric social worker understand, arrive at a social diagnosis and plan out the treatment of mentally ill clients. Thus these courses tend to stress psychiatric analysis of individual problems rather than skills in dealing with the core of the problem situation itself. They are also institution centres and stress the remedial aspects in mental health (Miranda, 1985). At the level of theoretical training mental health is not seen in its wider sense with contributions from other courses on social work methods. Specialisation courses are so compartmentalised that students of psychiatric social work generally cannot take courses offered by other specialisations like community development or family welfare, even though the information content of these courses may be very relevant for the psychiatric social work student to develop a holistic understanding of her field of training.

Field work is the practical component in the training to become a psychiatric social worker. Field work experience, in which the student is attached to various social work agencies for two or three days per week for the entire period of the training, is largely limited to institutional urban settings like child guidance clinics, mental health day care centres, and psychiatric departments in wards of urban hospitals. Here the student gains maximum experience in casework or in working with individuals who are diagnosed as mentally sick. Any experience in community mental health is usually unplanned and incidental. It is expected that when students become practitioners they will be able to transfer their skills to other settings. This never really happens. In field work students spend more time learning about the "what" and the "how" in field work tasks than in engaging in the "why" or analytical and conceptual learning (Miranda, 1985). Hence, students are more bothered about what are the symptoms and how to counsel a mentally ill person than in understanding why he has been labelled as sick, and what were the forces in his immediate and extended environment which caused him to behave in a different way than is normally expected.

Field work is critical learning experience for the social work student because this is the period when her concepts about the practice of the profession are being formed, based on her practical experiences; she is also trying to work out her professional role as a social worker. Relating theory to practice becomes the major learning activity in field work. When theory and practice focus exclusively on the mentally-ill person and on his treatment so as to get him resocialised and readjusted to the demands of society, it is inevitable that by the end of the training period the student social worker has equated working on treatment and rehabilitation of mentally ill persons as the main role assigned to her. She in turn becomes a practitioner and carries on this tradition.

Relevance of Training

Observing the practice of psychiatric social work today, it would appear that the effectiveness of the training is limited to the time tested casework method. However, as Desai (1981) says, the effectiveness of a profession depends on the quality of preparation of the practitioners. The objectives of the curriculum in social work training are to prepare the type and quality of manpower capable of performing tasks and functions which ultimately achieve the goal the profession has set for itself in the context of the society in which it seeks to serve. Desai analyses and lists the social realities of India as poverty, population and its interface with problems of housing, water supply, sanitation, accessibility to services; unemployment, disability resulting from social and economic inequity, and the exploitation of the vulnerable and weaker sections of society. Constant coping with these problems could lead to a breakdown in an individual's mental health functioning. Therefore the tasks of the (psychiatric) social worker would be to identify policies and socio-economic structures which are exploitative of the majority and which are not designed to achieve social goals for all. A second major role would be to develop and/or modify services and/or institutional structures for educating people to recognise their inherent capacity for action. By and large psychiatric social workers do not perform these roles because neither at the training level nor at the practice level has it been consciously realised and acknowledged that it is these societal problems of daily living which are contributing to the mental ill health situation in India.

The present day training programmes do not address these tasks. The training curricula are basically borrowed from the west, mainly the USA. They aim at helping people adjust to an urban, industrial and metropolis dominated social milieu—because Indian social scientists accept the western model of

development for the elimination of poverty. Social work was established to help the deviants of the system to adjust to it and to provide remedial services to those who are victims of new social systems (Desai, 1981).

The training and practical efforts of psychiatric social work is relevant; to whom it is so is the question. If serving the needs of the majority of the population in order to bring them into the mainstream of development is the goal of social work, then the training for psychiatric social work, particularly the knowledge about what constitutes mental health and mental ill health, the skills in treating mentally ill persons based on the understanding of what constitutes mental health, and the values embedded in such an interpretation are not relevant to the majority of the people, not even particularly to the mentally ill. Social workers have not been able, in any significant way, to work out strategies to deal with the daily problems of living of the majority—problems which take their toll in terms of familial tensions, and mental ill health. What the professions involved in mental health have successfully done is to medicalise social problems, to make it appear that problems stemming from social causes are actually due to individual deviance, solvable or at least controllable by the individual's doctor (and others involved in the therapeutic process) (Ehreinreich, 1978). Psychiatric social work, in this sense, is very relevant to the powers that be; through the semblance of a profession based on scientific knowledge, which helps deviant people adjust, it ensures that the way society is presently organised is maintained.

UN List of Banned Products

LAST June, the UN decided to delete all trade information from future editions of the "UN Consolidated List of Banned and Severely Restricted Products", an international directory of trade and regulatory data on over 500 products contributed by 60 countries. Just this week, the UN announced its intention to reverse that decision. The reversal came after months of lengthy debates on the issue within the UN in a highly politicised atmosphere. Ultimately, reason pre-vailed over pure politics and the public interest perspective—including trade data—emerged as the only rational solution to the debate. The 1986 edition will include trade data and the unique trade name index for pesticide and pharmaceutical products.

Hundreds of very thoughtful letters from the NGO community were in a large part responsible for allowing the debate to occur at all and for eventually helping to turn the decision in the direction of including trade data. While opposition to the mere existence of the 'List' has clearly diminished over the past several years, it has not disappeared. At the present, claims are being made that the 'List' is not really useful to governments, but is only a duplication of other efforts at information sharing laready in place in other UN agencies.

The United Nations is currently preparing its report on the Consolidated List Project for the Economic and Social Council (ECOSOC) meetings to be held in July. The office preparing the report would like to include examples of instances where the List has been useful to governments. The UN has recently written letters to countries in order to collect that information from them.

NGOs could be helpful in supporting the UN effort to collect data on the List's usefulness in a number of ways:

1 Encourage your government to reply to the UN's request for information. The UN has sent requests for information on the 'Lists' usefulness to World Health Organisation correspondents, United Nations Environment Programme correspondents, and the United Nations Development Programme's Resident Representative in all countries, and have asked those Reps to contact government officials for that type of informaton.

2 Contribute your own examples of how your organisation has used the List to bring about positive changes in laws or practices in your country. Brazilian groups, for instance, have used the UN Consolidated List in their efforts to persuade their government to severely restrict certain very dangerous pesticide products. A British organisation has reported that it has found the List very useful in its work with the United Kingdom's Food and Environmental Protection bill.

If you do send data on positive contributions of the 'List', please try to make your descriptions as specific and as well documented as possible. For example, it would be helpful to include the date of any legal or administrative action taken and a copy of the actual taxt of the law with your description of the action. If it is impossible for you to collect background documents, but you know of an action that has been taken as a result of the UN 'List', please report it anyway. Background can be collected later, if needed. All information must be received by May 15, 1986, it is to be included in the UN's format report for the Economic and Social Council. The UN address is: Assistant Secretary General, United Nations, DIESA-PPCO, 18th floor, New York, New York 10017; USA. Also, please send a copy of all correspondence to us for our information.

The Ambivalence of Psychoanalysis

david ingleby

Almost since the beginning of the century, psychoanalysis has sat like an undigested meal in the collective stomach. Unable finally either to assimilate or eliminate it writers have endlessly churned over its merits and demerits. The list of books on psychoanalysis which are offered to the public year after year never ceases to amaze. For, as well as being one of the most daring and radical ideas ever put forward, psychoanalysis is also part of a deadening and conformist apparatus. This paradox, which underlies the permanently troubled relationship between psychoanalysis and the Left is the subject of the article, condensed from "Psychoanalysis Groups Politics Culture" edited by the Radical Science Collective Free Association, 1984.

The Essential Ambivalence

WITHOUT doubt it is the ambiguous political message of psychoanalysis which has kept the discussion open so long. If it were possible to classify it once and for all as 'progressive' or 'reactionary', the issue would long since have been dropped. Writing a political character reference for psychoanalysis is no easy matter. So deep are the contradictions involved that one comes to mistrust anybody who has arrived at a simple conclusion 'for' or 'against'.

The political arguments against are well known. As a therapy, psychoanalysis can be authoritarian to the point of 'brainwashing' its patients; and concerned both with 'inner' factors to the exclusion of 'outer' ones, and with adjusting the individual to the *status quo*, rather than society to its inhabitants. As a theory, it is reductionistic, ignoring social factors and obscuring political tensions, and embodies many conservative and socially pessimistic assumptions. When this theory becomes disseminated as a popular world-view, we are in the grip of an ideology which stifles political action even before it can be expressed.

Yet as often as it is vilified, psychoanalysis is redeemed by leftist (and feminist) enthusiasts who come to its rescue. In the Frankfurt School tradition, it offers, first, a critique of the collective psychoanalysis which makes capitalism tick (Reich, Adorno, Marcuse); and, second, a mode of analysis—'critical self-reflection'—which provides a paradigm for 'emancipatory' thought (Habermas). In French structuralism (Lacan, Althusser), it decentres human subjectivity away from the Cartesian ego, in a paradigm shift as radical as that achieved by Copernicus four centuries before. For those seeking to give content to the slogan, 'the personal is political', it reaches beneath the banality of everyday consciousness to grasp the processes which underly the power-structure of relationships. Lacking any serious competitors on this terrain, psychoanalysis is likely to survive any denunciation its critics heap upon it.

We are not likely to find which side psychoanalysis is 'really' on by scrutiny of Freud's own political views. Aside from the fact that quotations can be dredged from his writings which show him in any light one pleases, the assumption on which such a search is based is a faulty one; there may be little correspondence between an individual's conscious attitudes to society and the message which speaks through their writings and actions.

The truth is, as I shall attempt to show in this essay, that the political character of psychoanalysis is *inherently* ambivalent; this is due, not only to the fact that different readings of it can be produced which argue in different directions, but also to certain contradictions built into its practice and theory.

Psychoanalysis As Therapy

The strongest criticisms of psychoanalysis as a set of practices arise from the fact that these practices are part of a system, labelled by Kovel (1980) the 'mental health industry', which basically exists because of its effectiveness in maintaining social order. Psychoanalysis shares with other types of 'mental welfare' concern to adapt or adjust individuals to their allotted place in society, by reference to an hypostasised set of norms of 'mature' human behaviour. Like them, it 'blames the victim' for his or her breakdown, leaving unscathed the larger social framework within which breakdowns occur. Seeing itself as a technology, it dehumanises its patients by submitting them to a rigid set of rules and modes of understanding; it infantilises them, the better to be able to control their development.

The same criticisms can be made of virtually any other aspect of the mental welfare system. It is a convenient oversimplification to say that this is because the system is based on psychoanalysis; in reality, the system is formed out of many different theories and practices, and what is visible of psychoanalysis within it is only the lowest common denominator which it shares with these other approaches. Berger (1955) may be right in claiming that, if Freud had not existed, American society would have had to invent him, but what this means in fact is that the success of psychoanalysis within the mental health system was (to use a favourite term of Freud's) overdetermined. Some of the determinants had little to do with Freud, and much more with the demands of the system.

That system, to a large extent, can be identified with psychiatry, but we must not overlook the dialectical change which psychiatry and psychoanalysis wrought upon each other. Unfortunately, most of the political critiques of psychiatry are focussed on precisely those parts of it which resisted this transformation; anti-psychiatry, and accounts of 'the medicalisation of deviance', have as their point of departure State-run, asylum-based, and physically oriented methods of treatment. Psychoanalysis, on the other hand, normally takes place with a private contractual relationship between client and professional; it is seldom institutional; and its method is purely verbal. Moreover, far from being something that can be imposed on people, it in fact demands from them a level of motivation which leaves many patients emotionally and financially exhausted. The continuity with nineteenth-century asylum psychiatry is an illusion; in reality, psychoanalysis resolved a profound crisis in mental welfare, by providing the *savoir* for new forms of intervention aimed at the population *outside* the asylum. Freud, of course, was not a psychiatrist but a neurologist, and from his out-patient practice he brought into psychiatry a method of dissecting everyday lives which the asylum doctors, with their largely cadaverous population of subjects, could never have developed.

A critique which can encompass psychoanalytic practice has to take as its starting-point a whole system for the management and surveillance of social life, the 'psy complex', of which traditional psychiatry forms only the backstop. The psy complex is an ensemble of agencies, including clinical, educational, developmental and industrial psychology, psychotherapy, and social work, whose discourses are not confined to particular sites of professional intervention, but which traverse the family, school

and work-place—indeed, 'the social' itself. The most effective ways of analysing this system have come not from anti-psychiatry, but from the 'post-structuralist' writers surrounding Foucault: Castel, Donzelot, Deleuze and Guattari.

Apart from the fact that these writers adopt a much broader definition of the mental health system than the anti-psychiatrists did, they diverge from the latter on three fundamental issues. The first concerns the relation between professionals and the State: whereas anti-psychiatry saw the former as agents of the latter – a kind of mental police force — writers on the psy complex emphasise its disorganised nature and its tendency to create its own goals. The second difference concerns the nature of the power exercised: for anti-psychiatry, this was essentially repressive, being concerned to stop people doing things they weren't supposed to. Post-structuralists, however, stress 'productive power' – the dissemination of discourses among a receptive population, discourses which shape and structure new forms of subjectivity. Lastly, whereas, for anti-psychiatry, the medical model and positivism played key roles in the legitimation of psychiatric interventions, the post-structuralists treat with contempt the notion of ideology and ideology-critique.

At least on the first two points, the post-structuralists' approach to the psy complex seems far more relevant for understanding psychoanalysis. (This is hardly surprising, for these authors to a great extent approached the subject by way of psychoanalysis.) For them, the growth of interventions in mental welfare has to be seen in the context of a gradual transfer of power from the family to other agencies.

With the decline of patriarchal power under capitalism, many of the traditional functions of the family in controlling and caring for individuals could no longer be exercised. The welfare state came into being through the piecemeal replacement of these functions by public agencies. Important among these, of course, was asylum psychiatry; but this came to be seen as not only an ineffective response to social ills, but one which came too late. Just as good drainage and physical hygiene had improved the physical health of the population, so analogous measures would guarantee its mental (and moral) health. The breeding-ground of all disorders came to be seen as the family, and it was on this site that measures were concentrated.

As Donzelot shows, a large apparatus was set up to monitor and deal with the 'failures' of family life, opening up in the process new avenues of intervention into the family itself. The achievement of psychoanalysis was to provide a systematic theory, a set of norms and a technology for regulating private lives. Some of its major advances were in fact made in the context of the two World Wars, when new opportunities arose to develop psychological remedies for military problems. Psychoanalysis achieved its dominant position within American psychiatry, however, by riding in on the wave of the Mental Hygiene Movement, which sought a radical reform and broadening of mental welfare services. This approach, with its emphasis on detection and prevention of mental disorder at an early stage, called into being a system as much concerned with socialisation as with care and relief.

The precise role of psychoanalysis within this system is perhaps the key issue that most sharply divides its supporters and detractors on the Left. According to Althusser (1971, p.178), the French Communist Party's rejection of psychoanalysis was based on a failure to recognise the travesty which American psychiatry had made of it: 'the "dominant" ideas, in this case, were playing their "dominating" role to perfection, ruling unrecognised over the very minds that were trying to fight them.' Lacan's more authentic reading would show that the biological and medical interpretation of psychoanalysis was, in fact, a heretical departure. Jacoby (1975) repeated what the Frankfurt School had argued all along, that psychoanalysis was not about 'nature' so much as 'second nature', quoting Marcuse (1962) as follows: "Freud's theory is in its very substance 'sociological', and no new cultural or sociological orientation is needed to reveal this substance." According to Jacoby, the authentic gloom of Freud's analysis of modern life had been excised for the American market, and replaced by a view in which achieving harmony between individual and society was merely a technical problem.

It is indeed true, as Paul Hirst points out (1981), that psychoanalysis has been by no means as universally influential in the formation of the psy complex as Donzelot and others assume. However, the mere fact that analysis remains a minority treatment should not blind us to the enormous influence that Freudian ideas have had on a wide range of forms of intervention. Even where an approach was adopted (such as learning theory) which nominally opposed psychoanalysis, such alternatives were fashioned in debate with psychoanalysis – a debate conducted in its own terms. And to complain that psychoanalysis was unwillingly co-opted into the mental welfare system is to ignore the prodigious efforts made by Freud himself to gain a foothold for it in the USA (see Castel, 1982, p.324).

This widespread dissemination of psychoanalysis, however, was indeed accompanied by a transformation of its original principles. Freud's ideas were only taken up in so far as they suited the aims of the psy complex; it would be as misleading to read off his views from the practices which purport to be based on them, as to try and infer Piaget's thought from the 'child-centred pedagogy' which claims him as its mascot (Walkerdine, 1984). In both cases, the take-up was selective, and one can imagine other uses to which the theories could have been put. To decide what psychoanalysis 'really' is, is like speculating about what Jill would be like if she hadn't married Jack twenty years ago; Jill may have had characteristics before the marriage which seem to have disappeared now, but on what grounds can we claim that this was the 'real' Jill? Nevertheless, in concentrating on the lowest common denominator which psychoanalysis shares with the rest of the psy complex, we may miss more essential features which set it apart.

The very lowest of these common denominators is something so obvious that one may easily overlook it – the *individualism* of psychoanalysis; the fact that it treats problems arising on social life in terms of the properties of individual subjects. It is the defining feature of all psychology that it takes the individual as the unit of analysis; Henriques et al. (1984) see this as intrinsically connected with psychology's functions of surveillance and regulation.

At the next level of specificity, which sets psychoanalysis apart from organic or genetic theories of personality, but leaves it undifferentiated from other environmentalist approaches, is the conviction that the determinants of individual dispositions are to be found in childhood, and that treatment can modify these dispositions. This, it will be noted, says nothing about the unconscious, or about sexuality, therapeutic technique, or the discontents of civilisation. To that extent it overlaps with the principles of behaviourist learning theory: Castel (1982, p.51) points out that, so far from being sworn enemies, psychoanalysis and behaviourism in the USA have often made a fruitful partnership. (It was J.B. Watson himself who suggested that 'any man in a position to serve in high public office should be obliged to submit to psychoanalysis.') But only a superficial acquaintance with the content of the two theories is required to see how much of Freud's thought must be set aside to make such a partnership possible.

Whereas the focus of intervention for the asylum system had been insanity, twentieth-century forms of mental welfare

concerned themselves with malfunctioning in everyday settings – 'failure to cope' (Armstrong, 1980). Such failures were encoded via the theoretical construct, 'neurosis', which – in the new sense which he gave to it – was Freud's chief gift to the psy complex. The concept of the unconscious, on the other hand, was taken up somewhat selectively by American psychiatrists. Rather than furnishing them with a critical perspective on bourgeois society, or a 'decentering of the human subject', it mainly served to reassure them that they could safely adopt a psychological approach without giving up their traditional claim, as doctors, to know better than the patient what was wrong with them. The notion of the unconscious thus played a central part in building a professional ideology for the psy complex (Scull, 1979). A theory which relegated the patient's own views about what was going on to the status of fantasy, and which took disagreement, or 'resistance', as a sure sign that the professional was in the right, did wonders for professionals anxious to secure their cognitive authority as experts on the field of human subjectivity.

As I have remarked above, classical Freudian therapy was by no means the main contribution of psychoanalysis to the psy complex. Such treatment was too expensive and time-consuming to be suited to more than a tiny minority of cases: for other patients, and other fields of intervention, new 'psychodynamic' methods had to be evolved. The most obviously recognisable are the post-Freudian, neo-Freudian, and even anti-Freudian forms of individual therapy, which sprouted prolifically in the fertile soil of the American market. In addition, Freudian principles were extrapolated to the construction of institutional regimes, of which group therapy was the mainstay; in this case, the object of transference became the group, rather than the doctor running it. When such methods were employed in the construction of therapeutic communities, we see a remarkable revival of the moral treatment pioneered over a century before by Tuke and Pinel. The aim of both treatments was to recreate the family environment in which disorders had supposedly arisen, this time under strict technical control, so that the deep-seated problems could be 'worked through' in a new context.

Other forms of intervention did not use Freud's prescriptions regarding therapy, but instead took his notions about development and family life as their guiding principles. Social workers, for example, did not ask their clients to free-associate or produce dreams, but they commonly understood the client's attitude to them in terms of 'transference', and attributed their problems to the insidious workings of unconscious fantasy – rather than to real social difficulties, which they had no mandate to remove. Agencies concerned with the promotion of norms of family life (such as family or juvenile courts) looked to psychoanalysis for the normative principles which defined a 'healthy' upbringing (e.g. the notion that boys need a father in order to grow into men). The wide range of services designed to monitor and regulate the environment of early socialisation (child guidance clinics, parent education courses, early detection schemes) was founded on the Freudian dogma of the infantile origins of neurosis – even though actual psychoanalytic theory was from time to time deemed unfashionable. John Bowlby's 'attachment theory', for example, is a set of ideas which have been highly influential in forming pedagogic attitudes and public policy, based on a bowdlerised – or should one say Bowlbyised? – version of analytic theory.

Wider afield, we may note the influence of psychoanalysis on marketing, on industrial organisation, and educational practices. Finally, there is the dissemination of Freudian ideas into popular culture. This process, which by-passes the professional nexus, is an aspect of what Brinkgreve et al. (1979) term 'proto-professionalisation', and is perhaps the most far-reaching of the effects of psychoanalysis. In the USA, it has not merely restructured people's ideas about what would constitute an adequate response to personal difficulties; it has become a world-view. As Castel (1982, p.261) puts it, 'Psychoanalysis was the main instrument for the reduction of social issues in general to questions of psychology.'

To describe the political character of psychoanalysis, however, it is not simply to list the types of intervention which it informed, without describing the content of the interventions. What sort of values and social ideology were associated with the name of psychoanalysis?

Here we reach the kernel of the contradiction which forms the topic of this essay. For to characterise psychoanalysis simply as 'conformist' or 'libertarian', 'progressive' or 'reactionary', 'pro-family' or 'anti-family', is impossible; in reality, it is all of these things. This ambivalence can be traced to the essential paradox of the welfare system of which psychoanalysis forms a part. For at the same time as it maintains and reinforces traditional forms of social life – in particular, the family—the psy complex undermines their very basis, by taking away their rights to self-determination. To adopt a global metaphor, it props up the ailing regime of the family, by turning it into a puppet dictatorship or client state with no real autonomy. Thus, the psy complex does not simply reinforce the family, nor simply undermine it. In a subtle holding operation, it manages to do *both*.

This point is made most effectively by Donzelot (1979), who compares Freud's role in the social realm to that of Keynes in the economic. Just as Keynesian economics maintained the mainspring of capitalism—the profit motive—but brought it under political control with a system of checks and balances, so Freud devised a technology which enhanced individual autonomy in some respects, yet retained the family as 'the horizon of all individual paths' (op. cit., p.232). In doing so, he struck the necessary balance between 'the necessity of imposing social norms of health and education, and that of maintaining the autonomy of individuals and the ambition of families as a principle of free enterprise' (ibid.). (There is a further parallel between Freud and Keynes, which Donzelot does not remark, but which is pointed out by Hirst (1981): that the doctrines of both were significantly distorted by the agencies which took them up.)

Though Marxists have long emphasised the role of the family in physically reproducing and servicing producers and consumers, Donzelot's emphasis on the family as a generator of 'ambition' (what we might call 'the Dallas principle') points to individual identity and motivation. Ambition, in fact, is not quite an adequate term to describe the scenarios and compulsions which the family bequeathes to its offspring. We must also take into account the mechanisms described by Chodorow (1979), through which the urge to mother reproduces itself, and also the general process of appropriation of cultural resources posited by Vygotsky and elaborated by the Berlin school of 'critical psychology' (see Elbers). The more we study these processes, the more illusory becomes the opposition of individual autonomy and family structure; the two are, in fact, mutually constitutive.

The ambivalence of psychoanalysis in relation to the family lies in the fact that it can unmask, and potentially dismantle, the mechanisms which hold the family together; it can untie the sacred bonds which hold fast man and woman, parent and child, in its stifling embrace. Yet it can also use this knowledge to tie the bonds even tighter, if it chooses. The wealthy intelligentsia who were the first clients of psychoanalysis (and will probably be its last) sought an escape from conventions of family life and sexual morality which were seen as no longer functional (what would nowadays be called 'getting rid of your hang-ups'). Castel (1982, p.32) claims that the first adherents of psychoanalysis in the USA were 'in rebellion against New England puritanism and

moral conformity', and no doubt Freud served them well. Yet the extent to which such an escape was permitted was circumscribed by psychoanalysis itself; and there is little doubt that, especially in the versions produced for consumption lower down the market, psychoanalysis defended more traditional values than it opposed.

It did so chiefly by reducing the elements of human existence to the nuclear family (what Deleuze and Guattari (1977) term the 'mama-papa matrix'), and by insisting on the inevitability and universality of certain emotional patterns, notably the Oedipus Complex. (If you were unfortunate enough not to have an Oedipus Complex to start with, Deleuze and Guattari wryly note, the analyst would start by installing one for you.) In addition, the dominant American version of psychoanalysis (ego psychology) emphasised the reinforcement of the ego, that is, of the 'reality principle', which is as much concerned with social realities as with physical ones. By conflating the two sorts into one absolute and unquestioned principle, psychoanalysis reified the social order into a timeless law. Thus, the conservative effects of psychoanalysis were closely bound up with the theory underlying it—a topic we shall deal with in the next section.

We may analyse the political stance of psychoanalysis, not only in its attitude to family structure, but also through its dealings with the individual subject. Here, criticisms relate to the power-relationship between analyst and patient, and the picture (once again) is by no means straightforward.

The commonest criticism, from a liberal standpoint, is that psychoanalytic technique is authoritarian and manipulative; it exercises a kind of totalitarian power that treats the patient as an object, or at best a sort of child. Castel (1972) stresses that, despite the liberal connotations of 'free association', the power-relationship between analyst and patient is highly asymmetrical; the analyst, in the name of 'technique', banishes certain topics by treating them only as masks for other topics. Any questioning of the way the analyst exercises his or her powers, for example, is treated as material for interpretation only. This one-sided relationship parallels that to be found between professionals and clients throughout the rest of psy complex. Elsewhere (Ingleby, in press) I have argued that the power of these professions is very largely based on the parental nature of the relationship which is on offer. (To this it shoud be added parenthetically that the *style* of parenting offered has changed in recent years, away from an autocratic and omniscient posture towards a more democratic and 'client-centred' one.)

Yet it is too simple to regard psychoanalysts as paternalistic in the same sense as priests, doctors or social workers. What is unique in analysis is the fact that this 'transference' is quite explicit and becomes, indeed, the main vehicle and topic of the therapy. Though it looks as if the analysts are merely aiming to install themselves in the parent's place, the better to control their patients, it is paradoxically the aim of analysis to destroy the very scenario on which it is built. Analysts are supposed to act as a 'blink screen', in order to reveal the images being projected on to them. They are, in effect, playing at not being there, in order to demonstrate that the patient's attitude to them is not based on reality, and must therefore be given up. So, far from telling patients what to think or do, much of their efforts go into sidestepping the patients' attempts to get them to do just this.

In psychoanalysis, then, transference is like a ladder which is thrown away when the goal is reached; not to have 'worked through' it thoroughly is the tell-tale sign of an 'incomplete' analysis. The aim of analysis is a relationship thoroughly cleansed of all parental undertones, which enables the patient to dismantle the familial scenarios which have previously structured and dominated his or her life. Doesn't this sound like emancipation?

The critics, however, are not attacking the ideal outcomes of analysis, but what goes on within it, which is rather like a game of football played on a sloping pitch. What is constitutive of dialogue is the equality of the speakers—the fact that both sides respond to each other's utterances according to the same rules, and accept a commitment to respect each other's communicative intentions. A situation in which everything one partner says is routinely reduced by the other to the status of material for interpretation is clearly incompatible with this ideal. Indeed, as Lomas (1982) points out, it is probably rather bad for people—especially if they find relationships problematic in the first place. The lack of reciprocity between analyst and patient makes the relationship less than a human one: Freud's 'rule of abstinence' specifically forbids analysts from presenting themselves to their patients as *persons*.

Psychoanalysis, however, never set out to be a humanistic or phenomenological method. It is true that understanding another's point of view requires treating them as an equal in the dialogue; but if you want such a therapy, the analysts would say, you are free to choose another variety such as client-centered therapy or (better still) co-counselling. Psychoanalysis, as Ricoeur (1970) pointed out, is not a species of phenomenology, and its method can never be purely hermeneutical; its systematic mistrust of the patient's viewpoint is required in order to gain a leverage on resistance and to reveal the patient's compulsion to lie about certain topics. One dosen't enter into negotiations with the Unconscious. To be liberated from one's own self-deceptions, which is the sort of emancipation Habermas (1972) sees in psychoanalysis, one has therefore to forego the 'unconditional positive regard' enjoined on therapists by Carl Rogers.

But the problem with this ideal of critical self-reflection is: where do the criticisms come from? If they come from an authority regarded as absolute, the so-called emancipation leads straight back into domination. (This, in fact, is the basic criticism of 'critical theory'). Now insofar as the criticism of one's self-perceptions comes from the analyst in person, we have seen that the authority ascribed to this figure is but a symptom of immaturity, which is fostered only in order to eradicate it. The 'full analysed' patient is free to treat the analyst as a cognitive equal, whose interpretations may reasonably be rejected if one can come up with better ones.

To see the analyst in *person* as the locus of authority, however, is a basic error. As we have seen, technique requires that the analyst's person should be kept totally hidden (witness the placing of the chair behind the patient's head); the interpretations come, in fact, from the doctrines of psychoanalysis, which the analyst represents in much the same way that the priest represents the doctrines of the Church, ('Not I, but Freud within me. . .') Thus it comes as no surprise that the patient's interpretations can stand on equal terms with the analyst's; the acceptability of *both* depends on their conformity with the framework of psychoanalysis. What the patient submits to, is not the rule of the analyst, but the rule of *analysis*, to which the analyst is every bit as subject. The real authoritarianism of psychoanalysis lies, not in the domination of patient by analyst, but in the domination of both by a analytic doctrine.

This is not mere hair-splitting: it is the resolution of the paradox that 'working through the transference' abolishes the analyst's authority, while building up that of psychoanalysis itself. I would submit further that the relationship to psychoanalysis itself is also ruled by irrational, unconscious processes, and that *this* form of transference is never worked through, since the analyst is likely to be as thoroughly immersed in it as the patient. That psychoanalysis is a supernatural

authority of analysts, as well as for patients, is betrayed by the curious behaviour of its practitioners towards their profession. To some extent their protectiveness is justified by the necessity of defending it from the real enemies that surround it; but their belief in its intellectual omnipotence, their obsessional preservation of its rituals (see Lacan, 1973), their scornful attitude to outside criticism and internal heresy—all these are more the hallmark of religion, than of a practice that claims to be the quintessence of rationalism. What the analytic community fails to understand is that it is not the truth of its beliefs which needs defending, but the grounds on which they are arrived at. Psychoanalysis can never claim legitimate authority if it is presented as a divine revelation.

We thus arrive at the conclusion that, although psychoanalysis is concerned with raising consciousness, and thus with raising certain powers of the self, it does so by attenuating certain other powers. Though productive, in Foucault's sense, it is also repressive; it demonstrates how wrong it is to regard productive power as *replacing* the repressive sort.

The way in which psychoanalysis 'produces' new forms of subjectivity, both for patients and in the culture generally, is the same as the process by which those around the child create his or her subjectivity in the first place. To understand this process, it is necessary to introduce the ideas of Vygotsky or Mead rather than Freud himself. The disclosure of psychoanalysis provides a framework of interpretations and implicit responses, in terms of which individuals may orient and articulate themselves; it thus gives them a 'position' within a discourse, in which to exist as subjects. Autonomy and awareness come into being in the space between analyst and patient (Ingleby, 1983).

This process also describes the productive effects of psychoanalysis within the culture generally. According to Foucault (1978), sexuality was not 'repressed' in the Victorian era, but endlessly talked about at a professional level; Freud did not shatter a silence, but merely transformed one discourse into another one. The discourse about sexuality (which had its ultimate origin in the religious confessional) embodies the codes which structure and regulate social life. Though these codes function 'productively', they are nevertheless imposed in a thoroughly 'repressive' way—as is also true, incidentally, of the codes within which subjectivity originates in childhood. Every discourse has a non-negotiable foundation which must be accepted as a condition of participating in it. As English people know from birth, there are things one simply doesn't talk about, and things one simply doesn't do: the child soon discovers that to certain 'why?' questions, the only answer is 'because'. It is in the parts of itself that the discourse does not allow to be questioned that its repressive power is concealed. In psychoanalysis, these parts are rather extensive. As Donzelot puts it (1979, p.230), 'the discourse of the psy professions credits the family with being both the only model for socialisation and the source of all dissatisfaction: it enables them to circumscribe the position of their clients, to mark out its circuits and block it exists.'

Psychoanalysis As a World-View

To bring in psychoanalytic theory at this point is not to change the subject: rather, to try to analyse the discourse of psychoanalysis as if it did not have an explicit and elaborate theoretical basis would be absurd. The theoretical counterpart of the 'familialism' embodied in psychoanalytic practice is the Freudian insistence on the elemental nature of certain types of family relation as the cradle of subjectivity. In this gaze, every influence on socialisation except that of the family is rendered invisible.

Not only does the family become 'the horizon of all individual paths', but it is a family frozen into the particular historical form in which Freud happened to find it. Marcuse may be right to argue that Freud's theory 'does not require the addition of a sociological dimension', in the sense that it places development firmly within the parameters of a basic social institution; but these parameters function exactly like constants in a physical law—they do not explain anything since they can never vary.

One might argue that Freud treated the social order of his time as a constant out of conscious conservatism, because he did not think there could be a better one; but in fact the theory that he wrought gave him very little choice, since it insists that this social order is the only possible one, given the 'human nature' out of which it has to be constructed. Freud did not see political ideals such as equality between the sexes, solidarity among mankind, or fulfilment in work as either practicable or desirable, save in miniscule amounts. This is because, on his view of human nature, alienation in all of its forms is inescapable. American psychiatry thus did not suppress the 'radical vision' of psychoanalysis, as Jacoby or Althusser would have us believe: there was no such vision to suppress.

The Inevitability of Alienation

For Freud, civilised man was inescapably at loggerheads with himself and with other men—and increasingly so as civilisation progressed. Both intelligent behaviour and social organisation entailed conflicts with human nature which made frustration inevitable: in Freud's metapsychology, the relationship between Ego and Id was essentially one of colonisation. This set severe limits on what could be achieved by therapy, and the optimistic project of using psychoanalysis to produce a happy reconciliation between individual and society—as American Freudianism sought, by and large, to do—was a hollow travesty of Freud's own philosophy. 'Transforming hysterical misery into common unhappiness' was the most that Freud claimed to do for *his* patients (1984/1954). Neither, of course, could Marxism free us from our chains, for the chains were part of our humanity itself.

To mitigate the severity of Freud's diagnosis, Marcuse (1962) introduced a distinction between 'basic' and 'surplus' repression—the former being that which was required to maintain civilised behaviour generally, the latter being added to this by forms of social domination. As far as Freud was concerned, however, the removal of 'surplus' repression would make hardly a dent in the sum of human misery. In the following sections I shall examine the different ways in which psychoanalysis can be thought to imply the inevitability of conflict. Freud's belief in this inevitability was, as he would say, 'overdetermined'; several different lines of reasoning led him to the same conclusion.

The Axiomatic Approach

Occasionally Freud makes it clear that for him, the opposition between 'reason' and 'instinct' is axiomatic, inherent in the concepts themselves. In accepting this presupposition, he was merely subscribing to the dominant conceptual framework of his time; that 'natural' desires were inherently 'unreasonable' ones was, for the average citizen of the nineteenth century, an unquestionable piece of wisdom, and we will be committing a pardonable solecism if we regard Freud as a typical Victorian in this respect. The dualism can of course be traced back to Descartes, and still further—although it was not without its critics, such as Rousseau, in the romantic epoch.

We see Freud elaborating this idea in his discussion of aggression in the case of Little Hans (1909/1956): Here, he refers to:

> . . . a universal and indispensable attribute of all instincts and impulses—their 'impulsive' and dynamic character, what might be termed as their capacity for initiating motion (p. 28).

The attribute, Freud goes on to suggest, lends to all conduct an aggressive (and, by implication, anti-social) character.

Horowitz (1977) demonstrates the same sort of preconception in his assertion that human drives are inherently 'distant from reality' (p. 9). Having accepted this idea, of course, Horowitz commits himself to a form of 'basic repression' that effectively pre-empts much of his subsequent discussion. A little conceptual analysis, however, soon shows that this notion is not a logically necessary one. For if what we mean by 'instinct' is simply an end which the organism innately seeks, then instincts have to be controlled merely because they lack form—not because they have the *wrong* form. In this sense it is a category-mistake to see an opposition between reason and instinct, because they are logically not the kinds of entities that can be in conflict. Rationality is concerned with means, instinct with ends, and insofar as rationality provides the means of gratification of instinctual needs, it removes a conflict rather than creating one.

Clearly, there are no grounds here for regarding the relationship between Ego and Id as one of repression; the relationship between cognitive and motivational mechanisms is essentially one of cooperation, not competition. Opposition can only arise because instincts themselves conflict with one another, or because the human mind inherits irrational modes of thought in addition to instincts themselves. However, making this elementary point does not go very far towards refuting Freud's pessimism; precisely such postulates form the basis of his whole theoretical system.

Elsewhere (Ingleby, 1983) I have tried to show that Freud's failure to explain the origins of rationality and consciousness comes from looking in the wrong place—in the individual, instead of 'the ensemble of social relations', and that this reflects a contrast between two world-views, 'Enlightenment' and 'Romantic', in terms of which most psychology remains rooted in the former camp. A theory of the social construction of the ego is implicit in the *practice* of psychoanalysis, and can be articulated in theory with the help of constructs borrowed from Mead, Vygotsky, and recent developmental psychology inspired by these two.

The Competitive Paradigm

I hope to have shown in the above that Freud approached the field of psychology with strong preconceptions about the inevitability of conflict between man and other men, nature and himself. (The conflict between man and woman is another part of the story, too, but one to which I have not been able to do much justice here. See however, Chodorow (1979, Ch.9).) In the case of libido, it is primarily because Freud assumes that the patriarchal nuclear family is inevitable that he sees frustration as necessary; primary process, however, constitutes an apparently innate mode of unreasonableness which militates against adaptation to *any* form of society. I have argued that it is the latter, cognitive postulate of Freud's which most seriously undermines a belief in social progress.

Though I am thus proposing that part of Freud's pessimism should be regarded as warranted, I have argued that most of it is not and it is therefore interesting to consider where his beliefs about human nature might have come from.

Chiefly, it would appear that it is Freud's tendency to ignore the social context of his observations that leads him to make the inferences he does. Freud's method was essentially ahistorical, in that he attempted to infer the nature of what had been repressed from its (unconscious) form after repression—without taking into account the possibility that whatever led to its being repressed in the first place might also have affected its form. Had he done so, the act of repression would have lost its self-justifying appearance, and Freud would have had to seek elsewhere the reasons for man's self-alienation.

For Freud characterises the Id in the same way that white Americans characterised the Red Indian, and colonial peoples generally have characterised the victims of their exploitation. The Indian had to be brutally repressed, so the myth ran, because his behaviour was lawless and wanton; likewise with the 'criminal violence' of the Algerians under the French—so coolly demythologised by Fanon(1967)—and so too with the lawlessness of children, mental patients, the working class . . . and the Id.

But these myths can only be sustained by leaving out of view the political facts of the case; the restoration of historical perspective brings back the justice and intelligibility of what has been repressed. We see that the domination and exploitation of the colonised person *produces* the characteristics which are supposed, by entirely circular logic, to justify it. Thus, the behaviour of the Indians does not reflect the intrinsic character of their culture, but that of the oppression they experienced; likewise, the 'seething chaos' of the Unconscious does not reflect man's biological predispositions so much as the savage force by which they are suppressed.

In order to understand what Freud found in the Unconscious, then, we must bear in mind the violence with which nineteenth-century Europe exploited its citizens—something to which Freud was remarkably insensitive, as his discussion of the case of Schreber demonstrates (Shatzmann, 1973). (For all this, we must hastily disavow the attitude that Freud's observations were somehow unrepresentative of civilisation before and after.)

Thus, we can see that the myth of inherent opposition between nature and culture was congruent with Freud's own conventionally conservative politics, precisely because this myth renders invisible the objective contradictions in society. Viewed in this light, Freud's theories seem not so much a challenge to the received ideology of his time, as a new and sophisticated reformulation of it.

What is this ideology? I have called it the 'competitive paradigm', because it sees any gain to one individual as entailing a corresponding loss to another. This, of course, is also the ideology of 'possessive individualism' (see Macpherson, 1962); although this view of society has its roots in the eighteenth century, it has enjoyed a sudden and spectacular revival in recent years, as part of the philosophy of monetarism. The concept of 'free enterprise' embodies an implicit assumption that enterprise which is free is competitive, because human nature is such that people would never of their own accord enter into cooperative arrangements. (The fact that even under capitalism, they persist in doing so, is always conveniently overlooked.) 'Laissez-faire' economies, instead of being seen as the forced contrivances which they are, are implied by their very name to be the outcome of letting things happen 'naturally'.

The assumption that 'free' enterprise is competitive entails, in turn, that cooperation in the common interest must be coerced; thus, socialism is identified *a priori* with iron rule and the end of liberty. Christianity is regarded in much the same light: for Freud, 'love thy neighbour as thyself' was a ridiculous and repressive injunction. 'The commandment is impossible to fulfil; such an enormous inflation of love can only lower its value, not get rid of the difficulty' (Freud, 1930/1961, p. 80). In short, therefore, we do not need to seek the origins of Freud's beliefs in his discoveries, his private political views, or his personal state of mind; they were very much a part of his time, and of ours as well.

The Necessity of 'Revisionism'

It should be clear by now that Freud's theories, in the form in which he left them, are not compatible with Marxism, or even with a liberal belief in progress. This raises problems for the 'new Freudians', who maintain that it is only subsequent 'misreadings' of Freud that have given rise to the impression of reactionary ideology. Jacoby (1975) sees Marcuse as 'unfolding' Freud's concepts into a revolutionary vision of history; but this 'unfolding' turns out to be of precisely the same kind as that of the conjuror who unfolds a handkerchief to reveal a flight of pigeons or a white rabbit. Jacoby is scathing in his attack on 'revisionist' versions of psychoanalysis—but without a substantial amount of revision, Freudian theory cannot legitimately be used for any but its traditional conservative purposes.

Of course, it may be the belief in progress which ought to be revised in the light of Freud; but in view of the foregoing discussion, I do not think Freud's arguments for the permanence of the existing order can be sustained—with the possible exception of 'primary process', to which I shall return below.

What would Freudian theory look like, then, if its more obviously ideological components were removed? I would argue that provided primary process remained intact, little of substance would be lost: the 'intertia principle' is neurologically false any way, the 'Death Instinct' is a speculative afterthought, and the inevitability of the patriarchal nuclear family was never a truly *psychological* postulate in the first place. A psychoanalytic account of child development which takes into account the infant's sociability already exists, in the British school of 'object - relations theory'. Obviously the question deserves a more careful answer than these few lines provide; but I do not think that the removal of ideological preconceptions from psychoanalysis would leave the theory either unrecognisable or unworkable. Unfortunately, until the necessity of this task is appreciated, progress on it is bound to be slow.

What of the remaining postulate, primary process? It could be argued that a species with such a talent for self-deception as Freud ascribes to the human race had but a miserable prospect of discovering a rational mode of social organisation, and could only make things worse if it tried to seek one.

However, primary process is not as incompatible with Marxism as this argument implies. Firstly, as we noted above, the theory that *all* thought is a delusion is self-refuting. Although Freud's theory of rationality is unsatisfactory, psychoanalysis needs such a theory in order not simply to be 'acceptably' optimistic, but to be coherent as a theory *at all*. Secondly, Marx himself (who incidentally shares this problem) places considerable emphasis on self-deception or 'false consciousness' in his account of the production and reproduction of social systems. Although self-deception for Freud operated primarily to maintain mental (rather than social) order, there is no reason why false-consciousness and emotional defences should not take the same form (the paradigm case being, perhaps, that of religion).

Hence, Freud is useful to a critical view of society not simply because he *describes* the inner conflicts of its members so faithfully—in contrast to the bland reassurances of 'humanistic' psychology; he also offers a detailed *explanation* of the compulsions and delusions which make people more at home in an oppressive society than they would be in a free one, and hence suggests what changes are necessary in order to make social progress psychologically possible. It is this psychological problem which Marxists after World War I, and feminists after the 1960s, turned to psychoanalysis to solve. Why was it that when the conditions for social change seemed ripe that people seemed emotionally incapable of accepting a new order? The Freudo-Marxists answered this question in terms of the 'normal neuroses' and compulsions which serve from one point of view, as emotional defences, and, from another, as social ideologies.

What Reich, Fromm, Marcuse *et al*, were essentially arguing was that a society which runs on fairy-tales *requires* that, in certain fundamental respects, its members should not grow up—particularly the less privileged ones; the task for radical psychoanalysis is to show how crippling compulsions arise in the course of *normal* socialisation, and persist because they serve so well the maintenance of oppressive institutions. Freud himself inevitably started this line of criticism by blurring the distinction between sanity and madness, arguing that religion, mass movements and character traits manifested the same structure (in psychological terms) as neuroses.

The development of a truly 'emancipatory' form of psychoanalysis, however, requires its disembedding from the system of practices—the spy complex—within whose constraints it must remain an individualist, adaptationist and essentially conservative form of praxis.

Newsclippings on Mental Health

Neglected Mental Health

IT is highly distressing to note that mental health is not receiving the priority it deserves from the government. An estimated 14 million people in this country suffer from severe mental illnesses. Besides, nearly 40 million people who include an increasing number of drug addicts and alcoholics, require mental care... (according to Dr. G.N.Reddy) a disproportionate amount has always been granted to technology at the cost of human health. It pains one to note that health, education and social welfare have taken the backseat... (according to Mohsina Kidwai) only 10 per cent of mental patients were being cared for at present as there were only 1,000 qualified psychiatrists, either working in hospitals or practising on their own in the country... and for every 32,000 people there was only one psychiatric bed (*Deccan Herald,* Bangalore, 20 August 1985).

No Hope for the Insane

The Lumbini Park mental hospital (Calcutta), set up in 1940... (has) no treatment facilities at the hospital, no surgical equipments ... not even an X-ray machine. Though there are six visiting physicians only one psychoanalyst works part-time at the clinic, while three resident physicians, two of them superannuated, hold the fort in their absence. This is hardly sufficient for the 160 inmates, 125 male and 35 female. The patients are kept in sub-human conditions and provided whatever meagre meal is available at a government subsidy of Rs.4 a day... Even drugs, requisitioned from the Central Medicine Store, it is alleged, are insufficient, if available (*Statesman,* Calcutta, 21 April 1985).

Clinical Depression

Depression, a modern term for melancholia, is a common mood (affective) disorder with a long ancestry. The others in this group of disorders are mania and anxiety neurosis... Nearly 100 million people in the world suffer from depression each year... A study from Chandigarh indicates that nearly 20 per cent of patients seen in general medical practice suffer from depressive symptoms with or without any physical illness... In a mental health survey carried out recently near Madurai, depressive illness was found to affect 60 persons per 100 among those aged 60 and above... The drugs which are used to treat high blood pressure, and psychotropic agents which are used for mental illness like tranquillisers, barbiturates, and hormonal preparations such as ACTH cortisone and contraceptive pills tend to induce 'iatrogenic' depression. There has been an increasing use of these depressogenic drugs over the years. The fast disappearance of the protective influences of the family and social support, a sense of 'anomie', a dessication of values, a mode of living bereft of ethics, and a state of 'existential despair', have contributed to augment the numbers depressed... Depression, a recurring illness, affects personal health, bringing psychological misery, precipitates domestic unhappiness, entails a loss of man-hours, and is a significant cause of mortality through self destruction (suicide) (*Science Today,* November 1984).

Ranchi Asylum Deaths: PUCL Report Indicts Government

A non-government inquiry conducted by the Bihar unit of PUCL has indicted the State Government for inhuman conditions in the Ranchi Mansik Arogyashala. Several hundred patients had escaped from this asylum last month... The Committee found that requests by the hospital managing committee to the state government to increase its annual outlay from Rs. 87 lakhs to over Rs. 2 crores went unheeded. The government allowed doctors' posts to lie vacant for years, sanctioning only 14 posts for nearly 1300 patients. Moreover, just one post of lady doctor existed for over 400 female patients. The Committee found no trace of nursing staff, nearly 80 of whom are supposedly employed. There was no staff room in any of the wards... The report said the mortality rate at the asylum has risen alarmingly from seven per cent in 1979 to 20 per cent in the first eight months of this year. In other asylums in the country the mortality rate is one percent. The report attributes the high death rate to government "indifference". The asylum's medical records indicated that a majority had died of prolonged malnutrition. Deaths were also caused by diarrhoea and dehydration. The Committee felt concerned that 58 patients had died over a span of 37 days... (*The Telegraph,* Calcutta, 21 October 1984).

Corruption in Mental Hospital

Relatives of the mentally ill accuse hospital staff (of Agra Mental Hospital) of corruption and callousness and of trying to fleece penurious patients. The staff they say refuse to admit those who do not have clout or cannot pay. The relatives, along with their mentally ill wards, have been forced to hire cots and live on the pavement. They struggle to cope with a situation which looks more hopeless with every passing day, aggravated by rapidly diminishing funds. Apart from paying for the cots, they have to buy food from the numerous shanty stalls that have sprung up to cater to the unexpected refugees. According to Dr. B. S. Yadav, senior medical superintendent of the hospital, patients coming from wealthy families are admitted to the paying ward which charges about Rs. 200 per month. For poor patients, provision of food, medicine and treatment is free at the general ward... Hospital sources allege that free medicines meant for poor patients are being sold... A visit inside the hospital has its own tale to tell—bare bodied patients in tattered khaki shorts cower in fright as guards force them to pull weed or cut grass in the fields (*Indian Express*, Bombay, 13 October 1984).

Mental Institute only in Name

The Institute of Mental Health, housed in the Alipore special jail, is still virtually a jail even though the state government declared it to be a mental institute for lunatic prisoners a year and a half ago. In fact, the government renovated the special jail and converted it into a mental institute for accommodating non-criminal lunatics (NCL) of the Dum Dum Central Jail with a promise to give them a fair deal... Investigations have revealed that only about 200 NCLs were taken to the institute from the Dum Dum Central Jail, out of a total of 800 NCLs languishing there (*Business Standard*, 1 October 1984).

Making of a Psychiatrist

anand nadkarni

The author is a practising psychiatrist as well as a teacher of the subject. In this article he looks critically at the training of a psychiatrist. He highlights the deficiency of the clinical approach and hopes for the emergence of a more socially relevant psychiatry.

PSYCHIATRY as a science never had a privileged position in medical education until recently. The picture has started changing slowly though not substantially. A major reason for this is the undue emphasis on the *biomedical model* of medicine in clinical training. An integrated or *bio-psycho-social model* of medicine even today seems a distant subject. I must confess that my comment is mainly based on my own experience in Bombay and some medical institutions in Maharashtra. But people will agree about similarities in the situation all over the country, with a few notable exceptions.

When I was on undergraduate student, not long ago, our month long clinical term in psychiatry was usually designated as a "leisure term" because we used to get only an optional short question (of 5 marks) on psychiatry in the theory papers of general medicine. The insistence by undergraduate students to take 'clinics', which usually takes resident doctors on an egotrip, was a privilege shared only by our medical and surgical colleagues. Things have changed of late. Students attend the term in psychiatry, and more sincerely. However, much of the credit for this goes to the introduction of a 35 marks section on psychiatry in the medicine theory paper by the University of Bombay.

Now, it is for the teachers in psychiatry to use this opportunity to inculcate genuine psychological awareness in students who will be general practitioners and consultants of the future. Recently one of our patients suffering from schizophrenia was advised by a medical consultant to get married, as that was the only remedy. Such statements although given (presumably) with a lot of goodwill underline the lack of basic psychiatric training given hitherto to the undergraduate students.

The average student, because of these lacunae, never ever develops a sound psychosomatic approach in his future career. Hence a patient complaining of persistent functional vomiting entering a general-surgical OPD of a big hospital first undergoes a series of investigations, including 'scopy', before being referred for a psychiatric evaluation.

This attitude of looking towards a patient as a mere 'case' stems from the basic lack of psychosocial orientation. Undergraduate students are never taught essentials of doctor-patient relationship, therapeutic effects of doctor-patient interactions, communication skills which can have both good and bad prognostic implications for the patient. It will be a surprising fact for some, but these subjects are not taught even to most postgraduate students of psychiatry. Virtues of spontaneity and intution are seldom stressed. Failure to master communication skills, makes us mere 'tic-markers' on the symptom check-list. Suppose I want to examine a four year old child in the psychiatry OPD, I make him sit on a stool near me. He has to literally strain his neck to look upto me. But suppose I place him on the table before me, our eyes come on the same level; I can pat his shoulder; I can also observe the spectrum of emotions on his face and corroborate it with his words.

Unfortunately we tend to cover up our failures to communicate under the term 'clinical distance'. To keep clinical distance between a patient and a doctor is one of the vague terms in an otherwise accurate medical vocabulary. If I visit some of my recovering patients' homes as a part of the process of rehabilitation, I am branded as a 'social worker' as if a doctor cannot and should not be a 'social worker' when the patient's welfare demands it. If a consistent bond of friendship is built between a patient and a clinician, which helps the medical bond then either the clinician is labelled as having a 'counter transference problem' or is simply ridiculed. Again, everybody in theory acknowledges the need for better communication, and everybody tries to explain the 'nobleness' of our profession on that basis. But 'doublespeak' is the rule of the day.

Most undergraduate studnets never grasp objectivity of mental status examination, during their clinical term. It has been a troublesome experience for me, when our clinical (mental status) examinations are often branded subjective; whereas even if two or more cardiologists argue on presence or absence of a murmur, the objectivity of their examination is never in doubt Fluctuating signs and symptoms is as much a property of schizophrenia as multiple sclerosis. This fact is often forgotten. One of my undergraduate students was amazed to note that 'insight' and 'judgement' could be really tested. He had thought of mental status examination as a mere data of inferences.

It is important to note that the average postgraduate student in psychiatry comes for his clinical training with such a background. In addition, I have often seen fresh entrants coming with a lot of dreamy notions about psychiatry. They think of it as a merely 'interesting' subject, something that is thrilling. During their period of residency their views usually get crystalised in the domain of biological psychiatry in contrast. After all the undergraduate biomedical influence tells, and that spicious by their absence in the postgraduate arena. But even a broad based psychosocial perspective is lacking. Average postgraduate students do not come to terms with the prevalent psychosocial reality of people from various stratas of society. Many students brand psychological and social angles as too theoretical and too abstract. Nor surprisingly, *psychotherapy techniques* never come higher up on the priority list for such students. Any psychotherapeutic work that the student does is only out of that perosn's own initiative and is hardly supervised. Wherever 'honorary' system for teachers is prevalent, this is likely to be 'the truth'. One of the essential therapeutic tools for a psychiatrist in our circumstances is to be conversant with

SUBSCRIPTION RATES

For two years now we have been bringing to you 200-odd pages each year of thought-provoking, analytical and often controversial reading matter for an incredibly low Rs 20/Rs 30. This has only been possible because we have been subsidising the cost from donations from some of you. Now, however, we are compelled to hike subscription rates because our production costs have gone up. We hope you will continue to support us despite this small increase in subscription rates.

Single copies: Rs 8 per copy

techniques of group psychotherapy. Many postgraduate students pass their examinations without even facing a single group. No wonder, patient-education is conspicous by its absence in psychiatry. Psychiatry students (postgraduate) seldom venture into explaining the essence of psychopathology in simple terms to the patient.

Not that postgraduate training is totally deficient; analysis and elicitation of signs and symptoms is taught upto the mark. At many places, training in psychopharmacology is adequate. What is not taught, is how to face many controversies in psychiatry with a balanced head. We are encouraged to take sides too early in our training. Hence we come out either as 'pro-ECT' or 'anti-ECT', to take one example. What is not realised is that such crystallisation of views essentially does not evolve from our own studies and clinical experience but as continuation of what 'boss' (i.e. senior teacher) is following over the years. Clinical training in general is more by precept than debate.

Because of our emphasis on western textbooks we tend to see many problems through their viewpoints. Let us take a concrete example of a young patient suffering from drug addiction. It is a widely noted observation that psychopathic personality traits are more common (either primary or secondary in origin) among drug addicts. Many of our urban addicts, especially from the working class, start the habit not because of these traits but because of ignorance about the whole process. Examples are coming to light from rural Maharashtra, where some unscruplous chemists had started giving unpurified heroin (brown sugar) as medicine to unsuspecting rural patients who approached them with a prescription note from the doctors. Some children in Bombay who earn money by collecting garbage have been lured by their area-goons into becoming brown-sugar addicts; many of them are in the age group between 9 and 11 years. The moral of the story is that any disease neds a dynamic question of oetiology and it cannot be rigid and puritan. We should also contemplate new equations and then try to analyse them.

I think, during our postgraduate training we let ourselves be moulded too much by our mileu. By mileu I mean the outlook of the institution in which we are trained, inclinations of our teachers and the general clinical value-systems adopted. A colleague of mine does not give an injectionof an antipsychotic depot preparation in the buttock of male schizophrenia oatuebt but prefers to give it in the arm so as not to arouse the latent homosexuality conflict which is thought to be present in schizophrenia according to the freudian school. His teacher believed in this and so does he. I personally think this to be too farfetched, though I must admit of having seen a couple of schizophrenics who had accusatory hallucinations with emphasis on homosexuality.

Most of our biases which arise from our training are because we tend to try and fit things into established, rigid models rather than using them as a base and then basing our interpretation in accordance with the unique characteristics that every patient brings in with him or her.

The entire medical training is devoid of the study of philosophical issues in medicine and a candid exposure to the student of social realities. This is all the more reflected in a branch like psychiatry where the *art and science* of medicine should meet. Usually any medico turns defensive when he hears the word 'philosophy'. Philosophical issues in medicine are both simple and complex, depending on your abilities to face them. One of the major issues, for example, is about the scope and function of a 'clinician'. Is it to be restricted to only 'clinical' situations? Should a clinician be a willing analyst of the wider sociomedical issues? Should he take an active part in community-health education? Should he attempt to make creative use of the media . . . In short, should he metamorphose a clinician with a global perspective or get tied down to consulting rooms and operation theatres? In theory, many doctors agree to the expanded role of the doctor but in practice it is hard to behave that way. We fail to understand that the so called 'busy' schedule and social interactions limited to cocktail parties, indicate a philosophical shift under the guide of practicality.

Hence any correction in the present status of training in psychiatry should be one which will influence the overall training in medicine. Only then it will be useful and different from the patch-work remedies. Unfortunately most of the experts on medical education believe that if the present structure of examination is changed then the content and quality of medical training will also change. Hence the emphasis till now has been mainly on examination reforms and widening of curriculum, on paper. Concrete plans and methods of implementation are hardly discussed as they are likely to threaten the existing biomedical structure. Well, there is something called the 'expert's paradise'.

Vol II: No. 1—Imperialism and Health (out of stock)

Vol I No. 1 and Vol II No. 1 are out of print. We can get the entire issue photocopied at Rs 25. If you wish to obtain individual copies of any of the other issues, please send us Rs 5 each per issue Vol I and Rs 6 each per issue Vol II plus postage of one rupee (ordinary post).

Different Voices

nalini

"In a Different Voice: Psychological Theory and Women's Development": Carol Gilligan, Harvard University Press Cambridge, Massachusetts, and London, England, 1982, pp 184, 5.95 dollars.

A THEORY is only a representation of truth perceived from a particular point of view. When theorists formulate psychological theories based mostly on observations of men's lives and find that women's experiences do not fit, it is the women who are held at fault, not the theories. Since theory performs the powerful function of validating one's perceptions, when psychological theory negates the truth of women's perceptions, are not the seeds of madness being sown? For society, all perceptions, experiences and behaviour, that fit into a particular predetermined mould, are considered normal, those that do not fit are considered abnormal. Does this then mean that women are by definition abnormal?

A man named Heinz considers whether or not to steal a drug which he cannot afford to buy in order to save the life of his wife. Two eleven-year-olds are asked to resolve this dilemma, which is one in a series devised by Kohlberg to measure moral development in adolescents by presenting a conflict between moral norms and exploring the logic of its resolution. In the standard format of Kohlberg's interviewing procedure, the description of the dilemma itself ... Heinz's predicament, the wife's disease, the druggist's refusal to lower his price ... is followed by the question, "Should Heinz steal the drug?" The reasons for and against stealing are then explored through a series of questions that vary and extend the parameters of the dilemma in a way designed to reveal the underlying structure of moral thought.

Jake, at eleven, views the dilemma as a conflict between the values of property and life, discerns the logical priority of life and concludes that Heinz should steal the drug. While taking the law into account and recognising its function in maintaining law and order, (the judge, Jake says, should give Heinz the lightest possible sentence) he also sees the law as man-made and therefore subject to error and change. Both his judgements, regarding what Heinz should do and the law being subject to change, rest on the assumption of agreement, a societal consensus around moral values that allows one to know and expect others to recognise "what is the right thing to do". Since his solution is rationally derived, he assumes that anyone following reason would arrive at the same conclusion, including the judge.

Amy's response to the dilemma is in sharp contrast to Jake's response. She replies in a way that seems evasive and unsure, and thinks that Heinz should not steal but find some other solution such as raising money somehow. According to her, neither should Heinz steal, nor should the wife die. She considers neither property nor law but the effect of theft on the relationship between Heinz and his wife. Even if Heinz saved his wife's life by stealing the drug, he might be sent to jail for it and then wouldn't be able to help his wife if she became sicker. So they should talk it over and find some way to make the money.

Unlike Jake, who is fascinated by the power of logic and considers the moral dilemma to be "sort of a math problem with humans", Amy views the dilemma as a narrative of relationships that extend over time. Her moral judgement is grounded in the belief that "if somebody has something that would keep somebody alive, then it is not right not to give it to them." She considers the problem in the dilemma to arise not from the druggist's assertion of rights but from his failure of response. Just as Jake is confident the judge would agree that stealing is the right thing for Heinz to do, so Amy is confident that "if Heinz and the druggist had talked it out long enough, they could reach something besides stealing." As he considers the law to have made mistakes, so she considers this drama as a mistake, believing that "the world should just share things more and then people wouldn't have to steal." *Both children thus recognise the need for agreement but see it mediated in different ways ... he impersonally through systems of logic and law, she through communication in relationship.* Just as he relies on the conventions of logic to deduce the solution to this dilemma, assuming these conventions to be shared, so she relies on a process of communication, assuming connection and believing that her voice will be heard, (emphasis mine).

The differences in the responses of these two children shows that infact they see very different moral problems in the dilemma. Jake responds to the question "*Should* Heinz steal the drug" whereas Amy responds to the question "should Heinz *steal* the drug." As can be expected these two responses receive different scores on Kohlberg's scale.

Kohlberg's six stages of moral development trace a three level progression; from an egocentric understanding of fairness based on individual need (stages one and two), to a conception of fariness anchored in the shared conventions of societal agreement (stages three and four), and finally to a principled understanding of fairness that rests on the free-standing logic of equality and reciprocity (stages five and six).

While Jake's judgements at eleven are scored as conventional on Kohlberg's scale, a mixture of stages three and four, his ability to bring deductive logic to bear on the solution of moral dilemmas, to differentiate morality from law, and to see how laws can be considered to have mistakes, points toward the principled conception of justice that Kohlberg equates with moral maturity. When considered in the light of Kohlberg's definition of the stages and sequence of moral development, Amy's moral judgements appear to be a full stage lower in maturity than Jake's. Scored as a mixture of stages two and three, her responses seem to reveal a feeling of powerlessness in the world, an inability to think systematically about the concepts of morality or law, a reluctance to challenge authority or to examine the logic of received moral truths, a failure even to conceive of acting directly to save a life or to consider that such an action, if taken, could possibly have an effect.

Asking different questions that arise different conceptions of the moral domain, the two children arrive at answers that fundamentally diverge, and the arrangement of these answers as successive stages on a scale of increasing moral maturity, caliberated by the logic of the boy's responses, misses the different truth revealed in the judgement of the girl. To the question, "What does he see that she does not?" Kohlberg's theory provides a ready response, manifest in the scoring of Jake's judgements a full stage higher than Amy's in moral maturity; to the question, "What does she see that he does not?" Kohlberg's theory has nothing to say. Since most of her responses fall through the sieve of Kohlberg's scoring system, her responses appear from his perspective to lie outside the moral domain.

Yet, the world she knows is a different world from that refracted by Kohlberg's construction of Heinz's dilemma. Her world is a world of relationships and psychological truths where

an awareness of the connection between people gives rise to a recognition of responsibility for one another, a perception of the need for response. Seen in this light, her understanding of morality as arising from the recognition of relationship, her belief in communication as the mode of conflict resolution, and her conviction that the solution to the dilemma will follow from its compelling representation, seem far from naive or cognitively immature. Instead, Amy's judgements contain the insights central to an ethic of care, just as Jake's judgements reflect the logic of the justic approach.

The above extracts represent the basic arguments set forth in Gilligan's book *In a Different Voice*. Her main contribution lies not in revealing sex differences, which she states have been noted throughout psychological literature. The importance of her contribution lies in discerning that these difference represent two entirely different yet cohesive ways of thinking and looking at the world. Consequently *unlike the interpretation offered by most developmental theorists that women's development is deficient because it does not fit into the male pattern, Gilligan interprets the difference as representing two different but equally valid patterns of development.*

Gender identity, the "unchanging core of personality formation" is "with rare exception firmly and irreversibly established for both sexes by the time a child is around three." Despite the fact that for both sexes the "primary caretaker" in the first three years of life is usually female, the interpersonal dynamics of gender formation are different for boys and girls. Since girls experience themselves and are experienced by their mothers as being more "like, and continous with, themselves," for girls identity formation is fused with the experience of attachment. In contrast, boys experience themselves and are experienced by their mothers as being different and separate, hence male identity formation entails a "more emphatic individuation and a more defensive firming of experienced ego boundaries."

From here on each sex starts off viewing themselves and others as if through a different lens. Gilligan says, "From the different dynamics of separation and attachment in their gender identity formation through the divergence of identity and intimacy that marks their experience in the adolescent years, male and female voices typically speak of the importance of different truths, the former of the role of separation as it defines and empowers the self, the latter of the ongoing process of attachment that creates and sustains the human community."

In the transition from adolesence to adulthood, while the dilemma itself is the same for both sexes, a conflict between integrity and care, a recognition of the need for intimacy becomes the critical experience for men, while for women it is the experience of choice. Since this conflict is approached from different perspectives by both sexes, it generates the recognition of opposite truths. This gets reflected in two different moral ideologies, "since separation is justified by an ethic of rights while attachment is supported by an ethic of care."

Criticising the one-sideness of development theory, Gilligan says, "Attachment and separation anchor the cycle of human life, describing the biology of human reproduction and the psychology of human development. The concepts of attachment and separation that depict the nature and sequence of infant development appear in adolesence as identity and intimacy and then in adulthood as love and work.

"*This reiterative counterpoint in human experience,* however, when moulded into a developmental ordering, *tends to disappear in the course of its linear reduction into the equation of development with separation*" (emphasis mine).

The real significance of Gilligan's work becomes apparent when we consider how development theory shapes the viewpoint of not just psychologists and psychiatrists, but also the general understanding of female nature as portrayed in humour, literature, the media. This has serious implications for the way in which women view themselves in relation to society and in turn how society views women in relation to itself.

Since women do not fit into the pattern of male development, they are considered to have a weak sense of self, an inability for clear thought and action, a lack of objectivity . . . This image of womanhood gets reflected in day to day interactions, and for women, becomes a very debilitating image of themselves to live with. "Women's place in man's life cycle has been that of nurturer, caretaker, and helpmate, the weaver of those networks of relationships on which she in turn relies. But while women have thus taken care of men, men have, in their theories of psychological development, as in their economic arrangements, tended to assume or devalue that care. When the focus on individuation and individual achievement extends into adulthood, and maturity is equated with personal autonomy, concern with relationships appears as a weakness of women rather than as a human strength."

For all of us, our sense of self depends on a validation of our perceptions from others. When women continually feel that they are not being understood or are somehow not saying the right thing, they become more and more unsure of themselves. "As the interviewer conveys through repetition of questions that the answers Amy gave were not heard or not right, her confidence begins to diminish, and her replies become more constrained and unsure." It is this sense of vulnerability, repeatedly heard in women's vioces, that "impedes women from taking a stand, what George Eliot regards as the girl's 'susceptibility' to adverse judgements by others, which stems from her lack of power and consequent inability 'to do something in the world'."

"Further, in a society where women have an unequal status with men, the above mentioned perceptions of women give men the 'right' to view women as inferior, especially since their views are backed by 'scientific theories' which consider women to be deficient. This also gives men the right to exclude women from direct participation in society, and women are thus forced to see themselves "as subject to a consensus or judgement made and enforced by the men on whose protection and support they depend any by whose names they are known."

According to Gilligan, the notion that virtue for women lies in self-sacrifice has "complicated the course of women's development by pitting the moral issue of goodness against the adult questions of responsibility and choice". For women the ethic of self-sacrifice is directly in conflict with the concept of their rights as individuals. This conflict also surfaces time and again within the women's movement, which has emerged in an effort to raise the collective demands of women and to struggle for their right to choose. Strangely, men, whose moral development is so much focussed on the question of rights, in reacting to the women's movement often revert from the higher stages of maturity to stage one or two of Kohlberg's scale of moral development!

The paradox of women's lives lies in the fact that the "very traits that traditionally have defined the 'goodness' of women, their care for and sensitivity to the need of others, are those that mark them as deficient in moral development." Yet if women were to be equally concerned with separation, autonomy, individuation, and their natural rights, as men are, women would cease to fit into the social roles assigned to them by society. Seen from this viewpoint, women would again appear 'abnormal', and perhaps their own family would take them to psychiatrists who would then attempt to make them 'adjust' better to society.

In this context, Gilligan's assertion of the need to broaden development theory, so that it encompasses the various dimensions of human existence, is a necessary first step. A broadening of development theory would mean incorporating the positive aspects of both male and female development as it exists at present. This would also amount to recognising that both male

Review Article

The Sorry Story of Psychosurgery

bindu t. desai

"The Stealers—Psychosurgery and Mind Control" By Samuel Chavin, Houghton Mifflin Co. Boston, 1978 $ 8.95.

'What is matter? Never Mind,
What is mind? No matter.' Punch.

THE human condition, through history, has always been marked with dread, anxiety, awe, fear, humbug and much confusion about the entity of 'insanity'. Everyone seems to know what it is, yet there is no general agreement about the whole concept of psychiatric illness, much less regarding the constituents of possibly specific entities like schizophrenia of hyperactivity. For instance, the diagnosis of schizophrenia varies with geography; it is made more stringently in Great Britain than in the United States or the Soviet Union where the condition mushrooms into subtypes (Szasz, 1976). It may have biological markers such as neurotransmitters or chemical messengers that affect the way brain cells work. However 'no unequivocal abnormalities' have been found in the neurotransmitters after three decades of intensive research into their possible role (Snyder, 1982). Both a genetic pre-disposition and as yet undefined infectious agent have been suggested as causative factors (Crow, 1983). Arguments continue whether schizophrenia is one disease or a group of widely different entities presently erroneously being lumped together, nearly a century after the disorder was identified (Hays, 1984).

There are other ill defined entities, that once appearing on the medical scene grow with time. The 'hyperactive' child in the U S or the 'maladjusted' child in the U K grew from three per cent of the U S school children in 1971 to 15 per cent in 1974, with about two per cent of all school age children receiving medications to control hyperactivity in that year. Hyperactivity is defined as: unmanageable, defiant, disobedient, aggressive, lying, truant, unable to concentrate, violent, overactive etc. No wonder Thomas Szasz calls all mental illness a myth—a category error. The brain can be sick says Szasz, but the mind is not an organ; "it is an abstract noun that lacks a concrete referant". (Szasz, 1984)

So we have a field of study where the entities themselves are not clearly defined, the possible underlying mechanisms ill-understood, the role and effect of mainstays of therapy like shock-therapy (E C T) and drugs (the major tranquillisers) controversial. In all of this for the past five decades there was yet another aspect—the surgical removal or destruction of a part of the brain to help or cure individuals with severe mental illness.

It is this form of brain-surgery or psychosurgery that Samuel Chavkin's book discusses, not only in a narrow medical sense but in its wider social and political context. On reviewing Chavkin's book on other related material, I am amazed at the virtual absence of any medical or scientific basis for psychosurgery and of the overwhelming social, political and cultural influences that determined the indications for it. For any surgery, say removal of an abscess or an inflammed appendix, the rationale is two-fold: non-removal will result in greater harm or fatality, and removal result in some alleviation or even a permanent cure. In a non-life threatening condition such as chronic mental illness one is presumably aiming at substantial alleviation if not a cure. Surely removal or destruction of as important and crucial a part of the body as bits of brain requires clearly defined entities at the outset, which have disrupted or incapacitated the individual's life and which no other form of therapy can help. The method of surgery itself should be a standard one so that identical areas are removed or destroyed at the patient's outcome judged not by the operating surgeon but by an impartial observer. None of this was true for psychosurgery.

The Historical Perspective

"This was the most unkindest cut of all" Julius Ceasar.

The history of psychosurgery, even as recounted by the strictly 'medical' account of Kucharski (1984), reads like a macabre piece of science fiction. In fact, the initial proponent of psychosurgery was a world renowned professor of neurology, Egas Moniz of Lisbon, who had invented the technique of cerebral angiography, a method by which dye was injected and x-rays taken to see the blood vessels of the brain. In 1935, Moniz heard two American neuroscientists present a paper at an international conference. They described the effects of destroying the prefrontal area of the brain of two trained chimpanzees thus: "the animal without frontal areas no longer appears to worry over mistakes. Whereas the normal monkey or chimpanzee may become excited, cry or have a temper tantrum or on the other hand turn away and ignore the problem after several successive failures, the subject lacking frontal areas seems quite impervious to any frustrating effects or errors" (Jacobsen, 1936). After the presentation, Moniz stood up and asked "Why would it not be feasible to relieve anxiety states in man by surgical means?" A few months later, Moniz's colleague Almeida Limm used alcohol injections to destory areas of the frontal lobe of a middle-aged woman with 'agitated depression'. Following surgery the woman was said to be markedly less agitated than before. After four patients had been operated upon, Moniz admitted that the patients were more apathetic than he had hoped. The four were sluggish, disoriented and incontinent. The alcohol that had been injected tended to seep further down into the brain than intended, and damaged vital centres that regulate breathing and blood pressure in the brain stem. The referring psychiatrist refused to send further patients for surgery.

But the era of psychosurgery had begun and in the next two decades nearly 100,000 individuals were operated upon (BMJ, 1971) in many countries including India (Valenstein, 1980). The operations were performed for a variety of conditions: aggression, neurotic depression, psychotic depression obsessive-compulsive neurosis, schizophrenia and other psychosis etc., with surgical procedures directed at different parts of the brain: the frontal lobe, the cingulum, the amygdala, or multiple sites. Moniz refined the technique of injecting alcohol to a leucotome—a mental rod with a wire loop that could be extended from its end to cut a bit of the white matter of the brain. In the U S A with true American expertise the technique was further simplified so that the operation could be performed in the doctor's office. Initially an icepick was used as a leucotome by the American psychosurgeon Walter Freeman because other instruments "dog-gone things would break. They weren't as good as an ice-pick."

(Shutts, 1982). The ice-pick leucotome would be forced through the skull immediately above the eye, and the surgeon destroy parts of the frontal lobe by manipulating the instrument. Moniz was awarded the Nobel prize for medicine in 1949 "for his discovery of the therapeutic value of the prefrontal leucotomy in certain psychoses".

Opinions on psychosurgery divided the scientific community almost from the beginning of the operation with proponents consisitently claiming that the procedure made it possible for patients who were suffering from crippling mental illness to lead normal or near normal lives. Others strongly disagreed. They viewed psychosurgery as a multilation of the brain to eliminate troublesome behaviour which turned the patients into 'vegetables'. Informed consent, that is, the patient's active consent to the procedure was not a factor in the decision to operate. Children too were operated upon.

All the while the operation rested on the basis that mental characteristics as different as creativity, memory, initiative and anger were transmitted via a fixed pathway in brains of the mentally ill. A normal person could be angry, happy or sad at various times, but not any of these all the time. Cutting the fixed abnormal fibres in the mentally ill would discontinue their sending the same emotion through the brain. Contrast Moniz's certainty with the comments of Phillips et al, in 1984. They are answering questions put by an imaginary individual who meets neurobiologists every 50 or hundred years. To the question "but can you tell me how the areas of the brain interact to display the integration evident in thought and behaviour?" The answer today would be "no". (Phillips et al., 1984). Surgeons who had performed hundreds of leucotomies were themselves aware of the lack of any physiological basis. One of them, Dr Harry Solomon had been asked by the Veterans Administration in 1948 to "describe the rationale of the operation at somewhat greater length and in terms of pathologic physiology". Solomon replied that a discussion of the rationale "would of necessity be very theoretical, and probably completely unsound. We would be better advised not to attempt it" (Shutts, 1982).

Not only did the psychosurgeons lack a theoretical basis for their procedure, 'they had no way of knowing what they had cut when they made radical stabs with their instruments' (Kucharshi, 1984). They failed to consider damage to blood vessels, or to make allowance for differences in skull size when they made their cuts. The fibres that were supposedly intended to be cut changed as autopsy failed to provide evidence to corroborate the surgeon's theory. Though editorials in the medical literature had repeatedly asked for carefully controlled studies to assess lobotomy (Finesinger, 1949) none were done. A long term follow-up of 707 patients who had undergone lobotomy four to 30 years before showed that 70 per cent of those hospitalised for less than a year prior to surgery were either still living in hospital or were at home in a 'state of idle dependancy'. (Kucharski, 1984).

The Recent Past

"That's the reason they're called lessons" the Gryphon remarked, "because they lessen from day to day." Alice in Wonderland.

The advent of major tranquillisers in the early fifties and their widespread use led to a decrease in the number of psychosurgical operations. However in the late sixties, these operations were advocated as a means of controlling urban unrest. Summer after summer in the years 1964-1968 American cities exploded in anger. In 1967 alone, there were riots in 127 cities as black people in the urban areas vented their frustration, despair and rage. Some Harvard doctors chose to interpret these riots differently, as follows.

"It is important to realise that only a small number of the millions of slum dwellers have taken part in the riots, and that only a sub-fraction of these rioters have indulged in arson, sniping and assault. Yet, if slum conditions alone determined and initiated riots, why are the vast majority of slum dwellers able to resist the temptation of unrestrained violence? Is there something peculiar about the violent slum dweller that differentiates him from his peaceful neighbour?

"There is evidence from several sources, recently collated by the Neuro-Research Foundation, that brain dysfunction related to a focal lesion plays a significant role in the violent and assaultive behaviour of throughly studies patients... we need intensive research and clinical studies of individuals committing the violence. The goal of such studies would be to pinpoint, diagnose and treat those people with low violence thresholds before they contribute to further tragedies" (Mark, Sweet, and Ervin, 1967).

Not surprisingly their view was popular with the U S establishment, for here social injustice was medicalised, racism not mentioned, the victims were blamed, declared to be mentally ill, suitable as candidates for 'scientific research', and possible psychosurgery. The letter caused a furore in the U S but was not without its defendants. The two main authors subsequently published a book called *Violence and the Brain* and continue to hold prestigious university appointments to this day.

Psychosurgery is performed very infrequently nowadays, but it has not been rejected by the medical community. It has an aura of respect, and its opponents are labelled as politically motivated, fanatic in their hatred etc. (Morley, 1985). Psychosurgery is a tragically perfect example that "science is not an objective truth machine, but a quintessentially human activity, affected by passions, hopes, and cultural biases" (Gould, 1980). Many examples of such science and of the pursuit of sociobiological determinism, its popularity and its extensive patronage by the rich and powerful are found in Chavkin's book. It is a chilling story which continues... Every field in biology is claimed as fortifying the belief that while "we may not live in the best of all *conceivable* worlds we live in the best of all *possible* worlds" (Lewontin, 1984). Needless to say such a world is capitalist with the white males at the very top. Biology is recruited to convince us that intelligence is genetically determined, that we have 'selfish geners', and that men are "compelled by their gender to be rogues" (Beckwith, 1984). For a reader who wants to know more about the sorry story of psychosurgery and the larger dimension of sociobiology *The Mind Stealers* can be highly recommended as a good introducton.

Doctors and Torture

A Report on Chile

AS the strength and awareness of organisations working in the field of health and medicine increase, they will have to identify newer areas and issues to intervene into the many social, economic and political processes in society. For only by generalising their intervention or activities they will be able to generate a health movement. One such issue is the alliance and complicity of the medical profession with the repressive apparatus of the state in both capitalist and post-revolutionary societies. There are many ways in which the individuals and the established organisations of medical profession help the state to better implement, cover-up and justify the repression and its repressive function. One of the most inhuman of them is the torture of dissident political activists and all other prisoners who refuses to submit to the wills of the law-enforcing personnel.

Democratic rights organisations in our country, as well as all over the world have taken up numerous cases of systematic violation of rights of dissidents, more consistently in the last 15 years. Interrogation, torture and other harassments with the complicity of medical personnel have been reported. They have also campaigned to build up public opinion and have pressurised governments on this issue. However, they have not been able to draw the serious attention of the organisations working in the field of health to the complicity of medical personnel in their inhuman acts. Such health organisations, due to their own weakness and the fact that they have started working independently only very recently, have not yet taken cognisance of the very political as well as medical nature of this issue.

A country which has witnessed the most brutal repression for over a decade has now shown the way. If the medical profession decides to fight, decides to genuinely observe and implement the code of ethics it always talks about, it can take positive steps in this regard. This is the country where a doctor social democrat, who also became its president tried to change the social order through parliamentary reforms and was overthrown by a military coup sponsored by the CIA. He and his supporters, and tens of thousands who protested were brutally massacred in 1973 by the military junta of Pinochet. Yes, this country is Chile, and the president was Dr Allende.

Action of Medical Profession Against Torture

A special report submitted by Eric Stover and Elena Nightangle of the Committee on Scientific Freedom and Responsibility, Washington DC, and published in the *New England Journal of Medicine* (October 24, 1985), under the title, "The Medical Profession and the Prevention of Torture" states that the Chilean Medical Association "has called on the military government to end secret detention, the situation in which torture is most likely to take place. Its leaders have met with members of the judiciary to press for the expedition of more than 200 complaints of torture that are stalled in court proceedings." This is indeed a highly politically conscious and bold act in a country where political dissent is dealt with bullets.

The leaders of the Association, of course, suffered for their boldness. Last August, Dr Pinto Castillo, a member of the Association's ethics committee and a Fellow of the American College of Surgeons, was detained by Chilean security forces. This act instead of demoralising these progressive forces in the medical community brought out a new mood of solidarity amongst them, and the medical and scientific associations in Chile, USA and other places came out in aid of Dr Castillo who was banished for 90 days to a small desolate island in Southern Chile without charging him with an offence. The international protest, however, had its effect and on August 22, 1985, 16 days after he was banished, the Chilean military dictators were forced to release him.

The Chilean Medical Association (Colegio Medico de Chile) was established in 1948 and has now a membership of more than 9000 doctors who constitute about 90 per cent of all medical practitioners in Chile. After the military coup of 1973, the Association, along with all other such professional bodies, lost its right to elect its own office bearers. However, this right was restored to it in 1981, and since then, it has played a key role in focussing attention in Chile as well as abroad, on the medical profession's complicity in torture. Dr. Castillo, other members of the Association have done painstaking work in documenting the use of torture by the state and in providing treatment to victims. Dr. Jaun Gonzales, president of the Association in November 1984, presented to the Chilean supreme court documentary evidence of cases of torture, and expressed his concern over the continuing practice of torture. The association has not restricted its activities only to Chile. In mid-1985, Dr. Gonzales along with Dr. Carlos Trejo, Chairman of its ethics committee, testified before the US Congress about the Association's efforts to stop professional complicity in torture.

Guidelines to Prevent Professional Complicity in Torture

Stover and Nightingale in their above mentioned report inform that the Association issued in March 1985, a set of guidelines instructing physicians not to attend to patients under certain conditions. This was as a follow-up to the Association's public statement in November 1984 warning that it would not allow itself to be "turned into a haven and bastion for people who transgress professional ethics". According to the guidelines, doctors should not attend to patients:

(1) If the physician has been ordered not to identify himself or to conceal his identify by physical means;
(2) If the physician encounters a patient who is blindfolded or hooded or otherwise prevented from seeing the examining physician;
(3) If the patient is held in a secret detention centre; or
(4) If contact between the patient and physican can be carried out only in the presence of a third party.

The association has also taken concrete steps to see that these guidelines do not remain on paper. It has held disciplinary hearings on the role of five doctors alleged to participated in the abuse of political detainees. They have also suspended one army physician, Dr. Carlos Herman Perez Castro, for certifying that a political prisoner who was tortured, was in a good physical condition upon her release from a secret detention centre. It should be added here that all such investigations and hearings are conducted by the Association in secrecy and public announcement is made only after its 20 member council reaches a verdict. According to Dr. Gonzales, the president of the Association, as many as 30 to 40 physicians have participated in covering up torture in the last one decade and they will continue their investigations till each is properly examined by the committee.

Although these guidelines were issued less than a year back, they have started to show positive effect. The Association's ethics committee chairman reported that after the guidelines were an-

nounced several military and police doctors had approached the members of ethics committee to report that they had been asked by the authorities to examine or treat prisoners who had been tortured. They also sought assistance from the Association in informing military authorities that they would not become involved in covering up torture.

In a backward bourgeois democracy like India, the flagrant violation of democratic rights of people is a routine affair. Our readers need no introduction on the daily torture of detenus carried out in a small police station to a well maintained torture chamber (like the 'retreat'in Calcutta) all over the country. The women prisoners need a special mention as they, in addition, face sexual abuse. In fact, the rape of a teen age woman triggered off a new wave of protest in the women's movement in recent times.

The democratic rights organisations have done significant work in making torture a political issue. No doubt, doctors have also participated in such organisations. The recent killings of a doctor, who was a prominent human right activist, by the police in Andhra Pradesh shows that individual doctors have played their role, even at the risk of their lives.

However, the medical community as such has much at stake in the system and therefore, its official organisations have consistently shunned responsibility to do anything in this matter. They did not have enough courage even to issue a statement when a doctor was killed for his human rights activities. Indeed, they will take a long time to learn from what their counterparts are doing in Chile. Thus, the responsibility is now with voluntary organisations of socially-conscious individuals working in the field of health to show courage, to build public opinion and agitate in the official associations to pressurise the medical community.

Secondly, at the same time, socially-conscious doctors will have to look into the medical aspects of the problem. As Stover and Nightingale suggest in their report, "physicians (particularly psychiatrists) need to become familiar with immediate and long-term physical and psychological effects of torture, for the purpose of diagnosis and treatment. Although research on the after effects of torture and the means of treating these effects is still in its infancy, recent medical research indicates that the major symptoms of torture victims, which sometimes occur years after the torture, include feeling of helplessness, heightened anxiety, impaired memory and inability to concentrate, nightmares and phobias. Publishing research on victims aids in the prevention of torture by informing the public of the pernicious effects of torture on victims, their families and society at large."

and female development, while complete in certain aspects is also deficient in other aspects. However, such a change would need to be accompanied by an effort at understanding how much of the pattern of human development is a result of socialisation and how much of it is due to 'inherent' or 'innate' human nature. Such an effort is vital, for without it, there is the potential danger of development theory recognising the importance of both male and female perspectives of development, yet drawing a clear distinction between the two patterns and declaring male and female nature as being 'inherently different'. As it is difficult to say different without saying better or worse, women may once again become victims of such a theory. Finally, since theory reflects a given social context, a change in development theory is likely to come about only when social conditions permit a change in our conception of what we consider 'male' and 'female' in the psychological realm.

OUR BODIES, OURSELVES

Organising Women on Health Issues

gabriele dietrich

This article tries to draw on experiences which were made while organising rural women in Tamil Nadu, mainly landless agricultural labourers of Dalit background. Health had not been a primary aspect in this process of organisation, it had been used as one of several "entry points", but as things developed, it turned out that health education became a focal point since it raises the crucial question of women gaining control over their own bodies. This control over women's bodies, as it emerged, is one of the most important factors conditioning women's potential to organise and to participate in decision making. This discovery came as a surprise because "health" is not usually seen as a high priority by village women themselves. The participatory research process itself was a means to build consciousness about such social controls and to find ways and means to break them down.

THE participatory research process which was part of a project of PRIA (Participatory Research in Asia), took place in villages near Arkonam, North Arcot among members of a voluntary organisation called Society for Rural Education and Development (SRED) and among women belonging to an independent organisation called Rural Women's Liberation Movement.

It is characteristic that even the formation of SRED as an organisation trying to facilitate rural women's movement, was already the result of a longer process of organisational experience. The initial attempt had been to organise Dalits (they were using the term Harijans at the time).

SRED today works in 50 villages of Arkonam and Thiruttanni taluks, 35 villages are "consolidated" villages where cells of the Agricultural Labourers Union and the Rural Women's Liberation Movement Sanghams (founded in 1982) have been formed, 15 villages are "new" villages in which work has only started recently. Women's Sanghams and Agricultural Labourers Union function largely independent of SRED. North Arcot, like Chingleput, is on the whole a very dry area depending on the monsoon which often fails. Irrigation will be by wells and village tanks. As in many other parts of Tamil Nadu, the water table has been affected by the bore wells. There are two crops, mainly rice, but also dry crops like ragi, maize and kambu (a millet).

Women agricultural labourers have 120-180 days of employment, men up to 220 days. Agricultural wages are as low as Rs. 6 for men and Rs. 4 for women. Supplementary income comes from wood-cutting and selling, also from brickmaking. The land holding pattern is such that there are largely small holdings and only very few cases of land concentration. This of course confines the scope for wage struggles within narrow limits. It is obvious from this background that the people with whom SRED works live in abject poverty and struggle for their very survival.

Integrating Health Work with Women's Organisation

The SRED did not start off as a health organisation. However, poverty being so rampant, health is clearly an important problem. Thus, health work came in mainly as an entry point for women's organisation. It was integrated with other activities like self-employment schemes: mainly embroidery and tailoring to start with, then mat-weaving, weaving of towels and sarees and carpentry. Plans are in process to branch out into cycle and transistor repair. Dairy and poultry schemes have also been tried.

In Arkonam, a special women's shop sells sarees and readymades. The effort to offer weekly opportunity for gyneacological check-up had to be abandoned due to lack of response. Apart from such attempts of income generation, building up rural women's organisation was the main objective. The Rural Women's Organisation has again and again taken up rape cases, wife murder cases, wife-beating cases, also issues like water supply and road building, accessibility of the village tank to *all* (i.e. including harijans and menstruating women) as well as health issues, much of the time by putting organisational pressure to make defunct government services available to the people. Recently, a journal Women's Voice (Mahalir Kural) has been launched to report on women's problem and the activities of Rural Women's Organisation. Again, the journal will also have a section on health, especially drawing attention to nattu vaittyam (indigenous herbal medicine). A drawback is that there are too many men on the editorial board because women lack training in journalism.

The basic concept is to equip women activists to be barefoot doctors, to have a basic understanding of common illnesses and treatments and to make them conscious of improving nutritional standards even under pressure of abject poverty.

The need for sustained health work first became visible in 1979, when a widow approached the organisation in need of an abortion. Since she was ashamed of expressing her problem straight away, she shrouded it in flowery expressions commonly available in village Tamil for this kind of occasion. (I have "not taken bath" for 2 months, i.e. missed the menses). The two young health workers did not understand her and sent her away with some aspirin. A few days later the village drums announced a death. The widow, in fear of ostracism, had committed suicide. It was decided to intensify health work and to link it up with rehabilitation of widows who are generally considered to be inauspicious and a social liability. A full time health worker trained in primary health was appointed and she took responsibility for training mainly middle aged and elderly women in primary health, among these a number of widows and village dais.

From the original 35 villages covered by SRED work, the women were drawn to get training as barefoot doctors. Since they are nearly all illiterate, the training went on for three to four years.

There are hardly any institutionalised health services provided by SRED. The community centre at Ulliambakkam runs a primary health clinic providing allopathic as well as nattu vaittyam (non-allopathic) services for common illness. Once in a week a private allopathic doctor comes voluntarily for consultation in more serious cases. At Kaverirajapuram, a cobblers village, once in a week a health clinic goes on under a tree with a homeopathy doctor who comes as volunteer. In Konalam centre, clinic work was started but had to be abandoned because of transport problem (it is inaccessible by public transport). At Mulvai a clinic was started with a gynaecologist, but this too had to be abandoned because of transport problem.

There are now eleven girls at the Kallaru centre who are working in self-employment schemes. Six of these also do part time health work. Three women full timers of SRED are appointed for training work in primary health. SRED has altogether eleven full-timers now (seven men and four women). Even the men animators who mainly work with the union and do work with men and women there, get all the primary health education with special emphasis on women's problems.

Emerging Concepts of Health

When health work was taken up by SRED, it was only partly integrated with the perspective of women's organisation. It was intended that health work should help to rehabilitate widows and would make basic knowledge of primary health available to a large number of women. However, the content of health education was rather complex and, as it turned out, rather contradictory. It cannot be claimed that all the underlying assumptions have been fully clarified but at least certain trends have become identifiable.

On the one hand, there was an attempt to make government health services available which would imply a curative allopathic approach. This was complemented by seeking the help of voluntary agencies working with an approach of preventive medicine along allopathic lines. This also implied a certain technical enlightenment about family planning methods, much along the lines of government programmes but without the coercive implication of these. The underlying assumption here was that use of family planning methods would automatically benefit women. On the other hand, there was an effort to enable women to really master their own health situation as self-reliantly as possible. This effort was undertaken by methods of nattu vaittyam mainly on herbal base, as well as cheap food supplements. The participatory method which was pursued, finally led to the insight that, instead of using health exhibitions prepared by experts, a team would be formed to prepare an exhibition, especially on the reproductive cycle and birth control. This led to a conflict with the technical approach pursued before and to the discovery that perceptions of sexuality were crucially influencing women's ability to apply birth control methods as well as women's ability to gain mobility and organise. Since these discoveries were an integral part of the participatory research process, it is necessary to follow this process step by step.

In the initial phase, a two day meeting took place, one day with animators of SRED and one day with about 30 women from the Rural Women's Liberation Sanghams. Initial discussions circled around questions like: (1) What are the most common illnesses? (2) How frequent are death in childbirth and child mortality? (3) How frequent are abortions? and so on. It turned out that all of these questions can only be answered within the overall context of abject poverty of the people in this area. Most common illnesses like diarrhoea, dysentery, fevers, breathing problems have all to do with general malnutrition, lack of water and basic hygiene and the constant worries of survival. Apart from this, some ailments were identified as occupational or environmental. There was widespread tuberculosis, probably with underlying byssinosis, among the workers of a cotton mill and there was a village where people suffered from water-induced paralysis. While death in childbirth is not a very frequent occurrence nowadays (partly because of the thorough retraining of village dais), child mortality remains high, especially among girls. Abortions were obviously widespread and a follow-up on this question showed that they are more rampant than assumed. While government services are available in a number of places, they are often defunct and in many cases people also do not have the money for the bus to go to the next health centre.

This overall situation accounts for some of the basic priorities in the health work which were pointed out: To strengthen self-reliance by teaching cheap basic nutrition and herbal medicine; to help to make existing government services available; to propagate family planning.

It was then decided to proceed with the participatory research in the following manner: (1) To document experience where people had organised in order to make government health services available to them. (2) To document the use of herbs, home remedies, indigenous medicines (nattu vaittyam) and to record the positive and negative experiences with such methods; also to document positive and negative experiences with allopathy in comparison. (3) To go more specifically into the question of *women* and health—how do women understand their own bodies? What is their understanding of the reproductive cycle, of birth control etc? Are information and contraceptives available? What are the social taboos? (4) In which sense is the health work an entry point for other women's work? How does it relate to the other work and to the process of getting organised? Why does this work pick up in some places and not in others? (5) What are the most important aspects of the women's work to the women themselves? Why do they feel it is an advantage to get organised? What are their difficulties in getting organised?

It was felt that in order to come to grips with questions 2-5, it would be necessary to have extended discussions and one way to generate them would be to conduct health festivals in different villages with exhibitions, skits, songs and pattimantrams (debate). Apart from the festival itself, the collective process of preparing it would give a lot of opportunities for exchange and clarification.

Already at this stage it became visible that there are indeed very strong social barriers against women taking control over their own bodies. It turned out that many of the village dais who knew everything about delivery, have a very rudimentary understanding of the reproductive cycle. Many women said they did not know about birth control methods. Some had used abstinence in order to space births.

The women said that the health work helped them a lot to build women's sanghams and most sangham members have an acute awareness of health and nutrition, so much so that many sangham leaders become free lance barefoot doctors and health workers. They felt that they learned a lot in the process and derived self respect from this. At the same time their competence about nutrition and simple illnesses also had increased their awareness of health as a business, the profits of the drug industries. Ironically, it seemed often to be the abject poverty which turned out to be a learning aid here. Since expensive nutri-

tional supplements and sophisticated medical services were out of reach anyway, the "do it yourself" approach looked like the only viable option. Among the slightly more affluent families, the drive for self-reliance would be less and the influence of advertising and impact of a consumerist allopathic approach to health more. It was also felt that the health topic needed to be discussed more in the agricultural labourers union and that building a new health system needs to be part of overall transformation of society.

Deepening Levels of Participation

Originally, the health festivals which were organised also included family planning propaganda. Though this propaganda was not particularly oriented towards achieving targets, it shared the commonplace middle class assumption that small families are necessarily happy families, that women only have too many children out of sheer ignorance and that women will happily apply family planning methods once they get acquainted with them. These assumptions had obviously been inculcated in the process of training health workers to propagate family planning and were not supported by the actual experience of working with village women. It became clear in the process of the participatory research where they went wrong and how they needed to be corrected.

A series of health education meetings were held with different types of people, e.g. the girls who learn tailoring in the Kallaru Centre, social workers, nurses, village dais, women who belong to the women's organisation. Apart from general health topics like hygiene, use of native medicine, etc. special emphasis was laid in these meetings in building up knowledge about the functioning of the reproductive system and to build up a different attitude among women towards their own bodies. This is no doubt an extremely difficult task, since everything related to menstruation, sex, childbearing and childbirth is usually taboo and it definitely belongs to the upbringing of a "good girl" not to mention about "these things". The general pattern is that "men are supposed to know" while women are best kept in ignorance. The underlying social assumption is that a girl who has any sexual experience, has been "spoilt". A further assumption often is that even "knowing about those things" "spoils" a girl.

It is also difficult to evolve methods which allow women to open up. One method is sharing personal problems in small groups of two and three. Another method is to talk about all parts of the human body and their functions in order to build an awareness that sexual and reproductive functions are as natural as any other functions of the body. Besides, slide shows were used about the reproductive system. On delivery, role playing has also been used.

There are different kinds of barriers to be overcome in different categories of participants in this kind of a programme. Among young participants, most of whom will be unmarried, there is a general embarrassment which has to be dealt with, giggling, and a certain reluctance to face realities. Among village dais and more elderly women from the women's sangham, there is greater sobriety in facing reality and drawing on one's own experience but the actual level of information is very low.

In a meeting with young girls in which I participated, the embarrassment was such that participants closed all the windows while slide show was going on so that nobody would be able to overhear what was discussed and the showing of slides was accompanied by exclamations and giggles. While the girls expressed afterwards that they found it useful to know all these facts, the question arises how they can be dealt with in real life since the actual taboo of knowing is so great that admitting such knowledge easily leads to accusations.

In another meeting with elderly women (village dais and women's sangham leaders) it turned out that though the women had experience and understanding about childbearing and delivery, many of them did not know about methods of birth control. Some of them had used abstinence in order to space child births. Some confessed to having had abortions. Some had reservations because they found it risky to go in for permanent methods because of child mortality. The tendency in the discussions was to place before the woman the options of birth control (e.g. loop and copper T, operation, etc.) in such a way that they appeared as the scientific way to go about things while abstinence from intercourse was looked at as unscientific and unnecessary infringement of the marital rights of the husband which would create tension and misunderstanding.

In the course of the discussions it became visible that the approach of the SERD animators was somewhat inconsistent. They had the tendency to depict tubectomy as a very good method of family planning because it solved the problem once and for all. It also transpired that, if a woman gets operated, she may have even less control over the frequency of intercourse than before because "nothing can happen" anyway. The man can assert his "right" over her body more easily since no risk of creating further offspring is involved. Woman also felt that they would face more accusations of infidelity if they used contraceptives. The animators applied a "harmony model" oriented towards fertility control only, suggesting that it was quite unnecessary and unscientific to deny a man intercourse in order to space births. It became visible that abstinence in some cases was a simple way of ascertaining sovereignty over one's body—an effect which could not be achieved with all the nice scientific technical methods which may in fact contribute to weaken a woman's control over her sexuality. Women also come up with their views that having to be sexually available hampered their mobility. They found it difficult to come for night meetings because they would be late in coming home. Even elderly women complained of the need to be sexually available very frequently. Sexuality was very much perceived as part of the sexual division of labour, women providing services and man consuming the same. It also became apparent that even women's access to hygiene is very much related to sexual division of labour as well as threat of sexual violence.

While certain general rules like tethering cattle or covering food can be easily followed, it turned out that women do not easily have basic access to hygiene. On being questioned about when they take bath, the usual answer is "on Friday". Friday is the day then they take bath, put turmeric, flowers and clean clothes and go to the temple. The men on the other hand have a daily bath. The problem is not scarcity of water because women may be handling water all the time, washing clothes, scrubbing vessels, watering plants. The problem is one of the division of labour and length of the working day. Women simply do not find the time to take bath. A bath is a luxury reserved for man. (Indeed, detailed enquiries into the working day of women and men among landless agricultural labourers have shown that women work up to six hours more every day.)

Another problem is the lack of privacy. It is more difficult for women to take a bath because women have to be constantly careful not to expose themselves to other men's eyes. This problem also affects their toilet habits. Women go to the fields very

early in the morning or late in the evening. The contradiction is that it should be dark in order to be less exposed, on the other hand, it is more dangerous to go out in the dark because of the danger of assault. All this leads to constipation and strain on the bladder. The problem gets aggravated during menstruation and pregnancy.

These conditions are so much taken for granted that it is extremely difficult to discuss them at all. It is extremely hard to think of any alternatives. Common toilets in the villages ("WCR toilets", a government programme) never work for lack of maintenance. One also wonders whether it is right to have public toilets for women and men in one cubicle just separated by a wall and with different entrances. If the toilets for women were in one locality and those for men in another, it might work better. Private toilets are entirely absent because of the money investment, water problem and fear of bad smell close to the living place. An experiment with a Gandhian dry toilet by two health workers was also given up. So at the moment, it is very unclear in which direction to go. However, by being able to slowly talk about the problem it becomes clear that the situation is quite unbearable and thus the motivation to tackle it slowly grows.

There are also questions about how to deal with menstruation. Women use old rags for sanitary towels and it should be explored whether it could become an avenue of self-employment to produce cheap sanitary towels at the sewing centre in Kallaru. It was also observed that bathing places for women have vanished over the last ten years due to environmental factors. Generally, the water table in the area has gone down because of bore wells. Many temple tanks have gone dry and others have been reclaimed for agriculture. Even where they still exist, the men are washing lorries in them. So the old custom of women going to the village tank to bathe, wash clothes and chat with each other has been abandoned. This not only undermines cleanliness but also women's solidarity. The question comes up whether the women's organisation can try to create a new place for women where they can wash, bathe, chat and spend some time together.

The Social Roots of Abortion

It transpired in the course of time that abortion is a much more gigantic problem than was evident from the beginning. In a discussion with middle aged and elderly village women it turned out that nearly all of them had experience with abortion, either undergoing them or performing them or both. Abortion is virtually a 'cottage industry'. It is usually carried out with home remedies as eating green papaya, swallowing large quantities of camphor and turmeric. The most widespread and most dangerous method seems to be the use of irakkan chedi (a plant the white blossoms of which are offered at Ganesh chathurthi). A dried yellow leaf of the plant is taken and the stick in the middle of the leaf is taken out and shoved up the birth channel into the uterus. This procedure causes ferocious infection and bleeding and any lead to severe puss formation and even blood poisoning and death. All the same, the method is widespread since it is free of cost and very "reliable" in the sense that the foetus does not survive. Often women have to go in for medical treatment in order to survive.

As far as infanticide is concerned, it remains a pious wish to say that girl babies should be treated equal with male babies. A substantial part of the problem of child mortality is in fact the problem of the morbidity of the social system of patriarchy. At the present moment, it is not yet visible how the women can go beyond discussions towards concrete solutions. The sobriety with which some of them admit infanticide is breathtaking and heartrending at the same time.

The facts of abortion and infanticide again raised the question why family planning is used only by a few. It was recognised in the course of the discussions that "family planning" as such is often resented as a form of government interference in family affairs. It is therefore much more meaningful to discuss the problem as birth control in the overall context of allowing women control over their bodies and over their health. The unpopularity of sterilisations is based on two factors: a) People shun irreversible methods because of child mortality, b) socio-cultural barriers. Men think they lose their "virility" when they get sterilised. They think they will be "weak" and unable to work sufficiently to support the family. There is also a feeling that a woman who has lost her fertility for good is treated with less respect. The problem seems to be that such "loss of respect" does not get compensated by a feeling of having gained control over one's own body because control over sexuality remains entirely with the man and may in fact be more than before. So the humiliation and actual subjugation which may go with operation may make it less acceptable than the risk of having abortions. Though the abortions entail great suffering, they are a matter of woman's own choice at a crucial moment and they are executed entirely among women. Thus, to get away from the abortions can only be achieved by means which would in fact enhance a woman's control over her own body.

Conceptualising Sexuality, Fertility and Male-Female Relationships

A series of 45 posters was made (basically using VHAI slides and *Our Bodies, Ourselves* as models) entirely on the the reproductive cycle, the sexual and reproductive organs, ovulation, fertilisation, pregnancies, the birthing process, cancer detection, sterilisation etc.

This exhibition has advantages over slides in that it can be used without electricity and that women can look at it at their own place. While a slide show just reels off under their eyes, they can go back to earlier posters for clarification, can contemplate them at length if necessary and ask for explanations. It is very important to be able to dwell on the problem at length because the actual embarrassment of facing one's own insides in this way is beyond all measure. Women admitted again and again to have been shocked at what they saw but they also expressed surprises, joy and pride. Even the health worker who explained the posters had to fight her embarrassment and had a tendency to rattle down the information in great haste in order to have done with it as soon as possible. It was later decided to avoid this and to first give the women a chance to react and to ask questions. One old woman objected violently: If women know all this in advance, how will they ever have the courage to get married at all. But young women counter-argued that this would support them to be less ignorant and helpless than before.

The exhibition was first shown in Ulliambakkam to about 50 women of different ages who had come from surrounding as well as far away villages. They were all sangham members. It was later shown to the girls in the Kallary centre who are in the self-employment training and partly in health training. When we discussed the exhibition in these different collectives, we discovered some lacuna in it which were later overcome as a result of these discussions. The 45 posters only dealt with the female body exclusively. It therefore did show tubectomy but not vasectomy.

This had done out of a feminist motivation to come to terms with "our bodies, ourselves". However, it was felt that this approach was not true to reality. The male contribution to pregnancy became visible only in the form of a few sperms, the

most expressive poster of this kind being that of a giant sperm wriggling its way towards the egg ("pampu pole"—"like a snake", as the women said). It was felt that there is surely more to getting pregnant than just that. Why did it seem to be difficult to face and depict this "more"? One underlying problem seems to be the sheer habit of exhibiting, exposing and even dissecting a women's body without great problems, quite in contrast to the actually imposed "modesty" and "shyness" of women. On the other hand, while men uninhibitedly and even shamelessly expose themselves, including their private parts in public while they relieve themselves, there is much more of a tamboo to actually depict a man's body, leave alone his genitals on a poster. This is one reason why we feel so free to dissect a woman's genitals and reproductive organs while we find it difficult to look at a man's penis and testicles with the same kind of detachment. It was therefore felt necessary to depict the man's reproductive system as well and to admit the involvement of the penis in intercourse. It slowly surfaced that there is a need to understand in greater depth the relationship between sexuality and fertility in order to come to terms with the overall problem of birth control and control over a woman's body.

The difficulty in doing this can be easily illustrated by the fact that one of the great revelations to women is the news that they actually have "three holes" i.e. urinary outlet, vagina and anus. Virtually none of the women were aware of this before marriage since there is total taboo on talking about one's body. One young girl said that she thought for a long time that talking to a man and laughing could make a girl pregnant since this was what her parents forbade her to do. Even when giving birth the first time, some women are still confused where the child actually comes out. In the posters, the female genital organs were entirely depicted from the point of view of fertility. The fact that women have a sexual organ of their own in the form of the clitoris which is not related to fertility was felt to be too much of a shock to be disclosed at this stage. The female body is seen entirely in terms of fertility, even as far as woman's own subjectivity is concerned. Women may be "male sex objects" but the question how they could possibly be subject of their sexuality and perhaps enjoy it, is kept out completely. Even women's protest against making women sex objects is often carried out by mobilising values of motherhood and nurturing. Women as sovereign sexual being seem to be unthinkable to women and men alike. However, this is not just a question of a women's general quality of life, it has quite devastating medical implications and at times becomes a question of life and death.

Men, on the other hand, are primarily seen in terms of sexuality, they are first of all sexual beings. The fact that their orgasm is achieved by ejaculation of sperm which make pregnant (while a woman's orgasm is entirely independent of fertility) is generally neglected. Since it is the woman who gets pregnant, fertility is "her" problem. But in fact "her" problem is that sexual satisfaction *in the man* is related to fertility. Precisely this is her actual health hazard. It was therefore felt that an exhibition on the reproductive cycle needs to depict these facts of life in a truthful manner.

Summing up, it can be said that the health work had focus entirely on problems of fertility which was seen as a "women's problem" which had virtually nothing to do with sexuality as far as the woman is concerned. Sexuality only came into the picture in the form of rendering sexual services to men who were seen as sexually starved and needy but had virtually nothing to do with fertility except that, unfortunately, the sexual act does make women pregnant. The task identified was therefore to acknowledge woman as a sexual being, to acknowledge the right to control her own sexuality to acknowledge man's responsibility for fertility which would also establish the necessity to see male sexual needs in relationship to female sexual and other physical needs and to the problems of fertility as a shared problem.

Perceptions of Marriage

These discoveries led to deeper discussions on sexuality and fertility and on thé actually existing patriarchal system of the family. It came out that women, while they see themselves as childbearers and as beasts of burden, most of the time experience sex as one more household chore like fetching water and firewood, cooking and serving food, finally surrendering their own body. These discussions were very interesting because the women felt free to speak out in a large group while at the same time a few of the men animators were also present so that there was a certain amount of interaction between women and men as well. Since men are seen as primarily sexual beings, the assumption seems to be that sex is their birthright and their supreme need, their "full satisfaction" an ultimate goal to which all other considerations have to be subordinated (e.g. refusal to use condoms). In a big meeting with fifty women only two said their husbands used them. On the other hand the sexual satisfaction of the women does not come into the picture. Since the men enjoy sex, they presuppose that women also do so. On the question whether they know what their women feel they said: How can we know, we have no words to talk about "such things". Men were completely taken aback when married young women said that they enjoyed caresses and tenderness while they often hated actual penetration.

Since "full sastifaction" of the man is the supreme value, the women needs to be ever ready. Women are often not allowed to go to night meetings leave alone to seminars which last several days, because they will not be available at home. The women are also frightened that if they do not provide these constant services, the man may shift to another woman and ditch them. Even elderly women face the problem of daily intercourse.

This led to the characterisation of a man's attitude towards marriage as a "facility" (Tamil: vasathi). Men get married when their mothers get too old to cook for them and they expect from it all the services like cooking, washing, health care, childbearing and rearing and sex. The one service they render in return is "protection"(pathukappu) which in fact only becomes necessary because of the general violence against women in society which makes marital rape preferable to the constant danger of indiscriminate sexual use, gang rape and the like.

It seems to be clear that unless woman's right to control their own bodies becomes an accepted human right, the use of contraceptives remains a remote possibility and women may go on for a long time undergoing home made abortions and allow their babies to die of neglect.

Discussions on Menstruation, Pregnancy and Delivery

In the workshop which accompanied the exhibition and which brought out most of the crucial insights which are summed up above, a lot of other information also came to light which, at a closer look, seems to be very much related to the social mechanisms which withhold from a woman control over her own body. All the women believe in seclusion during menstruation. They should not touch foodstuffs (especially pickles), should not go out, should not bathe and put flowers etc. They experience

themselves as impure and weak. They should not use disposable sanitary napkins because if some animal eats these, this will cause the fertilised egg not to settle in the uterus or early miscarriage. If menstruation ceases in a woman due to anaemia (which does happen since anaemia is widespread), this is ascribed to a "spirit". It is also related to the goddess Katteri. When they are pregnant, women are more susceptible to be possessed by spirits. They are also not to cross rivers and should avoid going out. There are the most comprehensive food taboos on pregnant women (on the list of foodstuffs to be avoided are : coconut, mango, papaya, jaggery, raw rice, grapes, bananas, jack-fruit, sweet potato, potato, maize, kambu (a millet), tinai (another millet) and a number of vegetables, including kirai, and eggs). Women are even restricted in their water intake. One really wonders how they keep alive at all with a diet chiefly consisting of rice and virtually nothing else to go with it. The idea is that the placenta may grow too big or that the child will be too big and delivery difficult.

Women are also kept in the dark about delivery. Since they are brought up in the belief that a spirit or a god leaves the child at the doorstep or that the old lady who sells vegetables has brought it along, they find it difficult to envisage the process of delivery even during first pregnancy. Some think the child many come out through vomiting from the mouth, others believe the belly may open underneath the naval. Some believe that the child comes out from the rectum. Some believe that the child comes out piece by piece, hand from hand, eye from eye and then gets assembled. Only three young girls had learned about pregnancy and delivery at school and one girl had got a rather realistic picture by overhearing other women talk about it. While exposures like the poster exhibition go a long way to set such beliefs right, a lot remains to be done to enable women to be in command of their bodies during delivery, by breathing exercise and methods of natural childbirth. It is quite a step to recognise that the pain during labour is due to contractions and that the most efficient way of dealing with it is not to clench one's fists and grind one's teeth while waiting for it to go over, but that there is an active way of combatting the pain by systematic breathing and relaxation. It is envisaged as a future step to go into methods of natural childbirth more systematically. It also remains to be explored to what extent this process can be explained to men and whether men can be involved in deliveries in a supportive way.

It is also important to see these prevailing superstitions about women's bodies during menstruation and pregnancy in the overall perspective of violence against women and oppression through perpetuated ignorance. The tendency sometimes is to ridicule women for their ignorance and superstitions. However, many of these are just an expression of concretely experienced powerlessness and isolation. Nodbody would nowdays easily come forward to blame a Dalit for his belief in untouchability. His mindset will be seen as the product of an oppressive system. Women's minds deserve to be understood in this overall framework as well.

Lessons Drawn

It is certainly not easy to draw clear cut lessons from a learning process as complex as the above described. One definite result is that the participatory research project itself has created more intense involvement and mass participation in the health education. Apart from this, the following observations can be made:

1. Certain contradictions were discovered between different objectives within the health programme, e.g. the activity of making defunct government services available and then dispensing health services rather at random, was in contradiction with the overall approach of using nattu vaittyam, making people subjects in dealing with their bodies instead of making them objects and consumers of treatment.

This is no doubt a very far reaching and complicated problem which can probably not be resolved on the ground of experience within SRED alone. Experiences of a more participatory use of allopathy have to be taken into account and also experience in the use of different systems (like ayurveda, homeopathy, yoga treatments) need to be absorbed.

2. Another contradiction which became visible was between organising and pursuing a very technical, propagandistic approach towards family planning, much along the lines of government programmes. In the course of the research this approach changed completely towards birth control in the context of establishing women's control over their own bodies and their own health, and becoming clearer about the link between sexuality, fertility and social controls.

3. During the change of approach, major changes in language became necessary, e.g. today it will no longer be said that a girl "has been spoilt" if she has been sexually used. Also, the traditional word karparhippy for rape (which means destruction of chastity) has been replaced by balat karama (sexual violence). While it may look surprising that all this should be part of a health programme, it touches deeply upon the underlying assumptions about and attitudes towards a woman's body.

4. It became increasingly clear thay many health problems cannot be tackled without tackling the underlying social root cause. E.g. the prevalence of illicit abortion and occurrence of female infanticide cannot be tackled without making the effort to break male sexual controls over women's bodies and transforming social relations and production relations within the family. Even access to basic hygiene is dependent on this.

5. It was felt that this is indeed quite a frightening perspective because it means overthrowing thousands of years of historical heritage. The question is how this can be done concretely. Some possibilities seem to emerge: (a) The discussion on the relationship between sexuality and fertility as reproduced above and the different impact it makes on the roles of men and women in the family and in society at large needs to be deepened in the women's sangham and among men as well. (b) Methods have to be evolved to help people, women and men alike, to face these new insights and to live with them. Since women in the village as a rule cannot walk out on their husbands, they have to find a way to survive in dignity as also to take a lead to transforming the relationship. Since women are traditional relationship-builders, they have the wealth of a historical heritages to own and to fall back on. Of course, their major objective should not be to redeem men but to learn to live their own lives. All the same, some redemption of man may occur in the process.

Apart from the need to collectively support women (e.g. against wife-beating in concrete cases or by holding seminars on rape, including marital rape), there will also be the need for individual counselling of persons and couples. If such counselling happens in the overall context of building women's movement, agricultural labourers union, health movement and people's science movement, the effects of it will be much more constructive and transforming than the normal opiatic marriage counselling or just technical advice on family planning.

The experience of SRED on the relationship between women's health and the structures of patriarchy in the family and society at large need to be shared with people working in the field but also in the women's movement, people's science movement and other mass movements.

Politics of Information

rosalie bertell

Recently two US women whose husbands had died of cancer due to radiation exposure filed a suit for damages against the company concerned as well as the United States government. This article, condensed from "Index on Censorship" (14: 5 October, 1985) reports how the US judge assigned to the case subordinated public health and safety to the interests of the government nuclear programmes. Nuclear advocates including scientists and scientific journals have applauded the judgement and have widely circulated it. What is being sought to be overlooked is that the judgement is not only biased but uses false scientific arguments and is full of obvious errors and misstatements.

TWO widows of cancer victims and two survivors of cancer among former employees of the Aircraft Instrument and Development Company (AID Co) brought suit against that company, 23 other companies and the US federal government, which has the ultimate responsibility for regulating industries using radioactive material. This case, cited legally as Johnston vs United States, 597 F. Supp. 374 (D.Kan. 1984), involved a company which purchased instruments with radium-painted dials at salvage for reconditioning. In addition to its regulatory role, the US government was the first owner of the instruments purchased by AID Co. The 23 companies had manufactured and marketed these instruments without warning signs.

The companies involved, after reviewing the plaintiffs' case, the expert testimony and their own defence, decided to settle out of court, jointly awarding $ 400,000 to each of the four plaintiffs. The federal government however, refused to settle out of court and launched a vigorous case defended by a team of seven US Justice Department lawyers in the US District Court for the District of Kansas. The judge was Patrick F. Kelly and there was no jury. After 42 days of testimony (5,509 pages of transcript), Judge Kelly closed the case of Johnston versus US government with a 150-page opinion issued on 15 November 1984, ruling against the plaintiffs and for the government.

The extraordinary aspect of this ruling concerns the use of this case to vilify three expert witnesses called to testify for the workers: Dr Karl Z. Morgan, Dr Carl Johnson and Dr John Gofman. To quote from Judge Kelly's written opinion:

> The paramount and obvious everriding interest (of this case) has been to 'put to rest once and for all, the likes of Drs Gofman, Morgan and Johnson'. . .
>
> The plaintiffs' claims are simply secondary to the interest of the United States.

He expressed the hope that his views of Drs Gofman, Morgan and Johnson would influence other courts in which they are scheduled to appear. On the other hand, Judge Kelly finds the US government's expert witnesses, Drs Maletskos and Auxier's methods 'wholly objective,honest and reliable'. Judge Kelly declared that he believed nothing of plaintiff's expert testimony and *all* of the government's expert testimony. He praised the government's witnesses as 'superb', 'eminent', 'the court's favourite witness', 'a refreshing and wholly qualified witness', 'wholly effective, honest and reliable'. 'brilliant', 'realistic and sound', 'impressive' and 'most convincing'. The opposite remarks were made about Dr Karl Morgan, Dr John Gofman and Dr Carl Johnson.

Judge Kelly's conclusions do not merely pose a question of unrestrained character defamation. They also represent a break with previous US court cases dealing with exposure to ionising radiation. Judge Kelly failed to quote or append to his ruling any previous court rulings, even the recent Colorado, Utah and Pennsylvania court decisions in which radiation injury settlements were awarded. In these cases the expert witnesses produced by the government failed to convince the court that exposure to ionising radiation at low levels was harmless.

Nuclear advocates have widely distrubuted Judge Kelly's conclusions. Both Cliff Goff and Dr Michael Fox, workers at the Hanford nuclear facility (a US weapon factory complex), have used it as the basis for letters-to-the-editor attacks on reporters who have quoted Dr John Gofman. Dr Sidney Marks of Battelle Northwest Laboratories—a former Atomic Energy Commission official who has tried to suppress the findings of excess cancer among Hanford workers as reported by Drs Thomas Mancuso, Alice Stewart and George Kneale—has handed reporter Karen Dorn Steele an underlined copy of the Kelly opinion. The February 1985 issue of *Nuclear News* contained an uncritical summary of the judge's opinion with no reference to the underlying scientific debate or issues in question. The magazine has never carried stories on the praise given these same scientists in other court cases.

The April 1985 *Newsletter* of the Health Physics Society contained the first article of a four part series called: 'Highlights from the Decision of Judge Patrick F. Kelly in the case of Johnson vs United States', by John R. Horan, former Chief of Radiological Safety, International Automic Energy Commission (retired 1983). This lead article gives some background to the Kansas event mentioning the case previously lost by the US government, the more than 4,000 lawsuits pending against the United States alone, and the 1979 decision of the US Department of Justice to devote 'the necessary time and effort to developing a team of specialised lawyers with the requisite scientific background and expertise'. It was this specially developed team which the US government used to fight the two widows and two surviving cancer victims and 'discredit' their expert witnesses in the Kansas court room.

This is an extraordinary way to conduct science. The first three pages of the Health Physics *Newsletter* contain nothing but exerpts from the Kelly opinion, without allusion to even one piece of scientific evidence or interpretation disputed before his court. Unless the readers had access to the 5,409 pages of trial transcripts they would have no way to test Judge Kelly's opinion on the health effects of radiation against their own opinions. Similar excerpted vignettes from the Kelly opinion have been duplicated by General Public Utilities, the company responsible for the Three Mile Island reactor accident, on 20 x 20 inch posters and sent all over the world.

What Is 'Safe'?

This extraordinary personal attack on three US scientists calls us to a serious study of its motivation. It requires, at the very least, a reflection on the basic scientific issues 'settled' by the court. The passing off of a judge's opinion which apparently endorses the nuclear industry and censures its critics, without issue discussion is unprofessional, to say the least. Never before have scientists appeared so needy of praise from a non-scientist as the nuclear community exhibits in this instance.

First let us look at Judge Kelly's logic. He repeatedly extols the Biological Effects of Ionising Radiation Committee (BEIR) of the US National Academy of Science as the 'world's irrefutable experts'. Although the BEIR committee states that

a 0.5 rem radiation dose to the general public yearly will result in 6 per cent cancer increase, 0.6 per cent increase in birth defects and a 15 per cent increase in ill health, Judge Kelly concludes to the contrary that there is no evidence leading one to expect radiation injury at exposures less than 50 rads (this is comparable to 50 rem). He states that even 72 rads may be safe. This conclusion of the court was not quoted in the Health Physics *Newsletter* or the other nuclear public relations material. The judge's notion of 'safe' is not clear, but certainly most persons in the Health Physics community would find even 0.5 rem per year to the general public 'not safe'. Judge Kelly's opinion (that allowing such high exposures carries no risk, is the 'international consensus among experts') is quite false.

Judge Kelly's preferred experts pronounced 40,000 picocuries of plutonium and americium a 'safe' body burden for atomic workers. In contrast, a US Department of Energy study showed a 33 per cent increase in chromosome damage among workers receiving 400 to 4,000 picocuries body burden. These studies of workers have also shown excess brain, lung, central nervous system and digestive system cancers, and leukemia (see *New Scientist*, 11 October 1984). Judge Kelly wrote: 'The four plaintiffs in this case have had numerous whole body counts (of radioactivity), each reported as negative, and which conclusively prove that they have no radium in their bodies.' This is in direct contradiction of the trial Exhibit No 12, 148, showing that the plaintiffs had whole body counts, performed by Helgerson Nuclear Services, which were between 132 and 330 times normal. The judge apparently confused the radium dial painters' exposure and the exposure of the plaintiffs to the hardened, flaked radium dust 10 to 20 years later. The GI tract uptake for the water soluble radium paint would have been much higher, and incorporation of radium in bone for dial painters was detectable with whole body scans. Three of the four plaintiffs were exposed primarily to inhaled radon gases and its decay products, not to radium. One plaintiff had cancer of the colon. For these types of exposure there is no expectation of finding radium, the precursor of radon gas, in bone. These facts were not conveyed to the Health Physics audiences.

The company at which the plaintiffs worked had dubious radiation safety practices. A letter from Mr Gaughan, Radiation Officer to Mr Fulks, Manager of Aircraft Instruments Development (AID Co) was also submitted to the court as evidence. The four workers with cancer had never been warned of the hazards of radium dials and pointers of the instruments they were re-conditioning or the dubious safety record of the plant. A US Occupational Safety and Health Administration inspection of the AID Co reported readings up to 100 mR/hr (a reading which would be normal for a year but not an hour) and over 2 million counts per minute (2 to 25 counts would be considered normal). It was only after the plant had operated for over 15 years that it first purchased an instrument capable

Now
CED offers its Documentation Service by POST.

DOCPOST

* low cost
* culled from over 150 newspapers and magazines
* over 500 information sources
* tailor-made to suit your needs
* saving your time, money and the bother

DOCPOST (Regular)—Ongoing clipping service in the topics of your interest.

DOCPOST (Spot)—Bulk material from our past files as and when you need it.

DOCPOST (Selective)—Copying of specific and selective documents and data from our documentation.

of measuring the beta and gamma radiation to which workers were exposed. It never possessed instruments for measuring the radon gas released continuously from the radium which was the principal hazard in the plant. The plant had received numerous complaints from the Kansas Department of Health and Environment because of its lack of radiation protection and the high levels of contamination throughout the plant. None of this worried Judge Kelly. None of this was reported to the Health Physics or nuclear establishment audiences.

The risk coefficients for cancer were another point of contention in the trial. Dr Karl Morgan was criticised for 'inflating' the predicted number of cancers. Dr Morgan had doubled the BEIR III estimates, a practice now accepted by Seymore Jablon, US National Research Council, and Dr Edward Radford currently correcting the atomic bomb survivor data on which the BEIR III estimates are based. On the other hand, Judge Kelly accepted the dose estimates for the plaintiffs calculated by Dr John Auxier, the person most responsible for the errors of dose calculation in the atomic bomb data (*Science* Vol 12, 22 May 1981). Since Dr Morgan made only a correction of 2 on the BEIR II cancer risk estimates, and did not use the added correction factor of 2 to 3 for conversion from absolute to relative risk, his cancer estimates would be generally considered conservative, ie too low, by most radiobiologists.

Justified Lying

The 'court's favourite witness', Dr Lauriston Taylor, perhaps gives us the best clue to understanding why the US specially prepared legal team was sent to Kansas to defend an obviously poorly run second-hand aviation instrument factory against the cancer death claims of two widows. He helps to situate the verbal attacks on the three scientists who tried to assist the court in coming to a verdict within the overall US predicament. Dr Taylor was quoted on Seattle television in February 1985, by Dr Richard Rappaport, president of the Seattle Physicians for Social Responsibility, as having said that lying to the public about nuclear matters is sometimes justified. As reported in the recently released minutes of the US National Advisory Committee on Radiation, 10 November 1958, Dr Taylor participated in the cover-up of a fall-out episode in Los Angeles caused by a nuclear test at the Nevada Test Site. The accident was described by Dr Edward B. Lewis of the California Institute of Technology as a 'really serious episode. We measured hot spots of about 2 mR/hr on the roof of our building and 2 mR/hr on our shoes... The real hazard is the inhalation of these in the lungs'. These exposures were much lower than those experienced by the deceased workers. In spite of the danger to the public, Dr Lauriston Taylor urged that the public be assured that all was well. In the 1958 minutes, Dr Taylor was quoted as having said that in order to actually protect the public from genetic damage 'you will have to talk about values set down by one hundredth or more'. He stressed that 'if you ever let these numbers get out to the public you have had it'. Birth defect rates have doubled in the US over the past 25 years according to a recent *New York Times* special report, but Judge Kelly wrote:

> This court finds that sincere and eminent scientists, like Dr Taylor, who have constituted the radiation protection community for over a half a century, have carefully studied all known literature on the carcinogenic potential of radiation and have set safety standards that were not expected to cause bodily injury during the lifetime of exposed individuals.

Just as Lauriston Taylor avoided public disclosure in the Los Angeles fall-out episode to safeguard the US nuclear weapon testing programme, so perhaps Judge Kelly found similar reasons to cause him to conclude that 'the plaintiffs' claims are simply secondary to the interests of the United States'. Those interests are the same in 1985 as they were in 1958, namely to convince people (however wrongly) that exposure to low level radiation causes no harm. Thus the American people will be willing to handle the uranium, run the nuclear reactors, separate out the plutonium, fabricate and test the bombs, and tolerate the radioactive debris from each part of the weapon cycle. The victims of this deception must be ignored because of the greater 'good' of national security in a nuclear age.

Although the Judge made many obvious errors and misstatements, these were not reported either in Donald Jose's letter, the Health Physics *Newsletter*, or the nuclear public relations material. The Judge referred to autoradiographs as audiographs; called the inverse square law the immense square law; thought MeV was a unit of power whereas it is a unit of energy; described alpha rays as bombarding tissues in millicuries per second; and said that electrons gave off daughter products. In a still more serious error, he claimed that there were no epidemiological studies or findings to support occurrence of cancer at radiation exposure levels below 50 rad.

The government lawyers used some rather crude tricks to convince the Judge that the radium handled by AID Co employees was harmless. They brought the dials into court and had Dr Robley Evans explain radiation threshold theory which was scientifically discredited in the late 1960s. This false theory led to an estimated 1100 excess lung cancer deaths among US uranium miners. They also brought into court a camping mantle whose beta emissions caused impressive clicks on a geiger counter. They failed to make available to the Judge the US Nuclear Regulatory Report No NU REG/GR-1910 , ORNL-5815, 1981, 'An Assessment of Radiation Doses from Incandescent Gas Mantles that Contain Thorium', which assessed the hazards of occasional use of such mantles. These two court-room demonstrations were used to minimise the years of work by the plaintiffs under unsafe radiological conditions at the AID Co plant. A special committee has been appointed to develop cancer risk assessment tables to estimate the probability that a particular cancer is attributable to radiation given the victim's age, sex, cancer type and radiation exposure dose.

The six-person committee is composed of three of the government's expert witnesses who testified against the plaintiffs who had lived downwind of the Nevada nuclear test site and who had contracted cancer. The government lost this lawsuit in Utah. None of the experts who testified on behalf of the persons exposed to fallout were asked to be on the Risk Assessment committee. None of the scientists who have published research papers on the cancer effects of low-level radiation were invited to sit on the committee. It is expected that the government will settle the 'scientific dispute' its own way—by legislative decree. This new tool will add to the effectiveness of the legal team with its scientific disinformation.

Why don't you write for us?

This periodical is a collective effort of many individuals active or interested in the field of health or interested in health issues. The chief aim of the journal is to provide a forum for exchange of ideas and for generating a debate on practical and theoretical issues in health from a **radical or marxist** perspective. We believe that only through such interaction can a coherent radical and marxist critique of health and health care be evolved.

Each issue of the journal highlights one theme, but it also publishes (i) Discussions on articles published in earlier issues (ii) Commentaries, reports, shorter contributions outside the main theme.

Our forthcoming issues will focus on: Health Care in Post-Revolutionary Societies, Primary Health Care, and Medical Technology.

If you wish to write on any of these issues do let us know immediately. We have to work three months ahead of the date of publication. A full length article should not exceed 6,000 words and the number of references in the article should not exceed 50. Unless otherwise stated author's names in the case of joint authorship will be printed in alphabetical order. You will appreciate that we have a broad editorial policy on the basis of which articles will be accepted.

We have an author's style-sheet and will send it to you on request. Please note that the spellings and referencing of reprint articles are as in the original and are NOT as per our style.

We would also like to receive shorter articles, commentaries, views or reports. This need not be on the themes we have mentioned. These articles should not exceed 2,000 words. Please do write and tell us what you think of this issue.

All articles should be sent in duplicate. They should be neatly typed in double spacing, on one side of the sheet. This is necessary because we do not have office facilities here and the press requires all material to be typed. But if it is impossible for you to get the material typed, do not let it stop you from sending us your contributions **in a neat handwriting** on one side of the paper. Send us two copies of the article written in a legible handwriting with words and sentences liberally spaced.

The best way to crystallise and clarify ideas is to put them down in writing. Here's your opportunity to interact through your writing and forge links with others who are, working on issues of interest to you.

WORKING EDITORS

Please send me Socialist Health Review for one year (four issues). I am sending Rs. _____ as subscription and/or donation by Demand Draft/Cheque. (D D and cheque in favour of Socialist Health Review and for cheque add Rs. 5, if outside Bombay).

Cancer Research

My agonies
are fed
into a computer
together
with five thousand
other women's
tears
terrors
hopes
relief
and despair.
We have been
categorised properly
to fit in nicely
there will be
a deathrate of course,
that is failure,
but most of us
will be a success
of modern science
and technology
of medical competence
and human endeavour
only no one
will measure
our resilience,
our love of life,
and the worries
about our children
There is no number
for the humiliations
we face when
they screw us open
to paint our uterus
from the inside
No one counts
the needles poked in,
the tubes inserted,
the bloodstained pads
the fact that
we will never be
the same again
making love.
And we are
grateful to them
for the tortures
inflicted
for they save
our lives
and we wonder
how they can live
doing this
every day.

Issues in 'Post-Revolutionary' Health Care

HEALTH care system and the health status of the people, like all the other aspects of social life, have undergone tremendous changes in those societies where the rule of capital has been challenged in a revolutionary fashion by the toiling masses. The class nature of the forces that led the revolution or of those which rule these societies at present, may be controversial, the direction taken by these societies after the revolution may be criticised, but the fact that there have been dramatic improvements in the health status of the people of these societies following the revolution cannot be denied. Conventional health indicators have shown amazingly rapid improvement (as compared to capitalist societies of comparable size, population and levels of development) in the USSR, China, Vietnam, Nicaragua, Mozambique and the East European countries. These societies are being categorised here as post-revolutionary (PR) societies. (We use the term 'Post-revolutionary' rather simplistically in place of the more controversial 'socialist', though we are aware that the use of this term too, is not free of problems.)

Several features distinguish the health care systems of the PR societies from those of the capitalist societies. They include, public ownership of health care institutions and allied industries like the pharmaceutical industry, the near absence of privatised medical care, free or heavily subsidised health care, rationalisation of health care delivery, strong emphasis on the promotive and preventive aspects, disease control by mass action rather than by biomedical interventions alone, decentralised control, integration of traditional systems and their practitioners into the existing delivery system and so on. Not that all of these could be found in any one or all of these societies. For instance, emphasis on decentralised control and self-reliance at the local level prevailing in China may not be found elsewhere (Sidel and Sidel, 1982). But one or more of these are generally to be found in the health care systems in all the PR societies.

Rapid changes in conventional health indicators characterised by steep falls in infant mortality rates; reduction in morbidity due to infections like tuberculosis, malaria, schistosomiasis and Sexually Transmitted Diseases (Sigerist, 1947; Alderguia and Alderguia, 1983; Quinn, 1973) and reduction in population growth rates cummulatively point to the improvements in the health status of the people. They have been brought about no doubt, as a result of better nutrition, sanitation and hygiene, easy availability of sale drinking water, improvements in housing, improved facilities for women (as compared to those in the capitalist countries), better medical care as well as better work environment indicated by more stringent environmental and industrial safety standards (Derr *et al*, 1982). The two most important factors responsible for these improvements, can be identified.

Rapid Modernisation and Abolition of Absolute Poverty: Though not a uniform phenomenon in all the PR societies, this has been the most important factor in improving the health of the people. This was made possible as a result of the defeat of the old bougeoisie and their allies in these societies. Now, whether the ensuing modernisation was 'socialist modernisation' as envisaed by Marx or not is a moot point. Similar quantitative improvements have also been seen in the advanced capitalist societies during the 19th and early 20th centuries and therefore, they by themselves cannot be said to be the characteristics of 'socialist' nature of modernisation in PR societies. Still, in the process, these societies were indeed able to meet the basic requirements of food, clothing, shelter and medical care of all the people, irrespective of their incomes and thus therefore, resulted in a healthier population.

Better Access to Medical Services: Medical services being by and large free and extensive, are easily accessible to most people. One's economic position does not prevent one from availing oneself of the best medical care available. This has indeed affected morbidity and mortality patterns in the PR societies.

But whether the health care structure that has emerged is really democratic and 'socialistic', operated by the working class possessing the necessary skills and knowledge is a debatable issue. There are indications to show that it is not. There are strong tendencies towards professionalism and technocratic control. One also needs to assess whether or not a sexist bias against women exists in the field of health care and medicine. Therefore, it is not adequate to apply only the conventional health criteria to assess the nature of the health care system and the health status in societies generally recognised to be different from capitalist societies. More sensitive indicators like comparisons of differences brought about in health and disease patterns in USA and USSR (or India and China), wage differentials among medical and health personnel, the proportion of women occupying high positions, the extent of homogenisation (narrowing down of sex, race, class, occupational and regional differences of health and disease indices) and so on need to be applied. Only such characteristics can differentiate a developed 'socialist' pattern of health care from that of a developed capitalist society. Whether the health care systems in PR societies has indeed reached such a stage is an issue requiring much analysis and discussion.

While noting the positive aspects of health and health care in the PR societies, one cannot fail to take note of several features which raise vital issues regarding the nature of health care in these societies, having wider implications outside the field of health and medicine.

It is noticed that indicators like life expectancy at birth, IMR and others have reached a plateau and are even regressing.

Also, a tendency towards overmortality of males over females is noticed (*International Journal of Health Services*, 1983; Gidadhubli, 1983) due to steep increase in cardiovascular diseases, cancer and accidental deaths. A similar phenomenon is noticed in the advanced capitalist societies also (see Doyal with Pennel, 1983). These diseases have been associated with over consumption, stress and other environmental factors. Whether high incidences of such diseases signify a life-style and an environment resembling those in the advanced capitalist societies or not is a question that needs to be resolved.

In the USSR, an increasing concern is being felt about the rise in alcoholism. Various legal and administrative measures have been initiated to curb this problem (Lindgren, 1985) Alcoholism is associated with psychosocial stresses. Under capitalism, besides other factors, a lack of creative pleasure in work, leads an individual to avenues of superficial pleasures. Alcohol is one of them. Is a similar process still at work on an increasing scale in PR society like USSR? This

rather uncomfortable question needs to be faced squarely in order to comprehend the real nature of the processes affecting the psychosocial health of the people in these societies. Another related indicator reflecting the sociopsychological disharmony is the incidence of mental disorders and suicides.

Though quantitative indicators of health do give an idea about the health status of a society, but it does not give the total picture. It can be shown that early development of capitalism also produced improvements in the quantitative indicators of health care. What it did not improve was the quality of health care: doctor-patient relationship has become depersonalised, the aged are marginalised; the mentally sick are heavily drugged and dehumanised. What is the situation in the PR societies? How and how much different is the quality of care to the sick, the aged, the minorities, the women and the mentally sick from those in the capitalist societies? What one finds would point to what could well be an important differentiating feature of a 'socialist' health care system.

In a capitalist society, medicine reflects and reinforces the bourgeois ideology. Thus, a disease is reduced to a biological phenomenon, ignoring the role-often a determining one-of social, economic and cultural factors in its causation. Such a view justifies the use of biomedical interventions causing a growth in the demand for industries producing the required technological inputs. On the other hand, the hierarchical relationships in the medical field amongst the medical personnel, between doctors and patients-reflects the bourgeois ideology of class, race and sex dominance. Now in the PR societies, how do health planners, doctors as well as people view health and disease. How are the relationships amongst various health personnel? These are questions of vital importance that should be resolved while assessing the health care systems of PR societies.

There have been disturbing reports of dissidents in PR societies being labelled as 'behavioural deviants' and of use of psychotropic drugs to bring about behavioural conformity. This is a blatant example of the use of ideology in medicine to serve the political needs of a class or a group by converting an essentially political issue into a medical problem. What are the compulsions that such practices persist in PR societies is also an issue related to the question of ideology in medicine in PR societies.

In some countries like Poland for instance, chronic shortages of drugs, equipments and staff are reported. (*International Journal of Health Services*, 1983) Now whether this shortage is real, that is as related to the needs of the people or false that is as related to the needs of the socially more powerful medical profession remains to be seen. A false shortage could be felt if there is a tendency towards overmedicalisation of life; by replacing community level health care personnels and paramedics by doctors; by the demands of doctors for more technological inputs of doubtful value and so on. If the shortages are indeed real, a study of the underlying socio-economic processes could reveal much about not only the health care scene of the society but also about the problems of 'socialist' reconstruction during the PR period.

Towards a Dialectical Understanding

Now, the causes of these problems and the underlying processes can only be understood in the context of the prevailing social and economic conditions of the existing social formation. An analysis of these problems brings us to the very crucial question of the relationship of a social formation and substructures thereof. Though developments in health and health care systems come under the influence of socio-economic factors in movement—that is of history—this relationship is not one -to-one and deterministic. It is a highly complex relationship of mutually dependant dialectical interactions. And therefore, each problem has to be understood within its specific historical and social context.

Thus, while studying health and health care in any social formation, one important point needs to be kept in mind. A 'socialist' health care system develops in the historical context of the process of 'revolution' and thus carries with it the stamp of the specific processes of the society with all their contradictions. Neglecting this aspect may lead one to an incorrect understanding of these societies as well as their health situations (Segall, 1983). One may be led to a narrow empiricist position; a position which adopts a static view of social structures and considers the health care system existing in a society as directly reflecting its socio-economic processes. Taking an isolated view of the events that went into making up the health care system in a PR 'Socialist' country, this position labels whatever exists there as being 'Socialistic' in nature. On the other hand, it may also lead one to take an idealist view constructing an abstract 'Socialist' model of health care devoid of any socio-historial context. Various characteristics are ascribed to such a model. Out of these, which constitute the necessary and the sufficient conditions for a 'Socialist' health care system are unspecified. Therefore, mere absence of a few characteristics of this idealised model, in an imperfect concrete health care system, full of contradictory tendencies of a PR society, leads one to label it 'non-socialistic'. Worse still, it denies the possibility of waging struggles to incorporate some of these feature into the health care systems of capitalist societies.

It would not be entirely out of place here to mention a related problematic of the role of struggles in a capitalist society to imparting to the health care system, some of the 'Socialist' characters. Whether a movement for greater social control over health care services and allied industries is a movement towadrs a 'revolutionary' health care system or not is a crucial question for those fighting for fundmental social changes. One exteme view, might see such a struggle itself as a revolutionary movement thereby overlooking the overall persepctive of such a system. On the other hand, an equally extreme view may call such a movement as 'reformist' as it does not touch the root-cause, thereby overlooking the vital importance of stages in the movement for 'revolutionary' health care. Several other factors like the leadership, mass mobilisation, methods used for raising people's awareness, modes of organisation and struggles also need to be assessed before making any judgment. A thorough analysis of the inter relationship of a health care system and a social formation would go a long way to resolve a constant dilemma faced by those involved in such struggles.

* * *

In this issue: Amar Jesani writes about the problems and process affecting health in Nicaragua; Malini Karkal discusses the population policy in China and Padma Prakash draws attention to the changes brought about in the health care system in Mozambique after 1975. Bob Deacon's reprinted article raises relevant issues regarding health and health care in the three post-revolutionary societies, Soviet Union, Hungary and Poland. And we introduce 'Update' a section for reports, notes and comments.

Health in Nicaragua

Epidemiology of Aggression

amar jesani

Though the Nicaraguan revolution is still fighting for survival against escalating US aggression, it has ushered in far-reaching changes in the field of health and health care. These changes are examined in this paper. The author refers to the role health workers played in the Nicaraguan revolution and discusses the post-revolutionary reforms introduced in the health care system and the consequences of US imperialism's continuing war against Nicaragua for the people's health. Health professionals, the author argues, will have to understand the epidemiology of war better since the world is likely to witness more revolutionary upheavals and crises as well as imperialist aggressions.

A QUARTER of a century ago, the victory of the socialist revolution in Cuba, till then the so-called backyard of the US imperialism, generated a new wave of revolutionary movements, not only in the Carribean basin, Central America and Latin America, but all over the world. The revolutions in Grenada (March 1979) and Nicaragua (July 1979) widened the breach opened in the imperialist empire by the Cuban and Indochinese revolutions. The revolution in Grenada was, however, crushed by US imperialism before the whole process could completely unfold and get fully consolidated. The revolution in Grenada nevertheless inaugurated changes in the health and health care system of that country, though it is beyond the scope of this article to deal with them. Also, the information available to us is very fragmentary to allow us to discuss the changes in detail. On the other hand, although the Nicaraguan revolution is still fighting for its survival against escalating US aggression, it has unleashed far more profound changes in all aspects of people's social life, including in the field of health and health care, enabling us to examine them in considerable detail

There are few regions which have been so much the object of the foreign policy of an imperialist power as Central America and the Carribean. It has been the theatre for permanent US intervention for 85 years. The US has always claimed the right to lay down the law there. It considers this whole region to be an integral part of its 'defence system' and has 40 to 50 military bases there and is building many new ones. In 1982-83, 20 per cent of entire US military budget was earmarked for this region. Behind this military involvement is the US economic interest in the area which is a major communications and trade route as well as a great raw material reserve and source of cheap labour power in the international division of labour (Fourth International, 1985, p 89). This is the reason why the countries in this region are kept strictly subordinated to imperialism to such an extent that the political regimes there are 'created' by the US.

The super-exploitation of people there by imperialism has led to deterioration of living standards to abysmal levels, extreme poverty, unemployment, and so on. The resistance to this exploitation has also grown so much so that people are in a state of permanent war with the military state machines. The health consequences of this continuous war are far-reaching, to the extent that the health professionals are suddenly required to scientifically understand the health consequences of war or the epidemiology of war and agression.

Nicaraguan Revolution: Historical Background

The Subjugation: Nicaragua, like other parts of Central America, was conquered in 1523 by the Spaniards and they subjugated the Chorotec Indians of the Aztec family. It become a centre for slave trade for more then three centuries under Spanish rule. It attained "independence" in 1821 and slavery was abolished in 1824 (Weber, 1981, pp 1-5). Ever since its "discovery" Nicaragua has always been of interest to the great powers. The US has militarily intervened in Nicaragua at least three times.

The first US armed intervention took place in the mid-nineteenth century at the time of California gold rush. This intervention, though short-lived, opened a way for US financial and political interests which, in the course of half a century, converted Nicragua into a coffee exporting country with a plantation economy. Coffee constituted 50 per cent of the value of Nicaraguan exports till the cotton boom of the 1950s. All exports were chiefly to the US. The second US intervention took place in 1909 and US forces continued to occupy the country from 1909 to 1925. When the US withdrew its forces in 1925 it thought that the regime backed by it would survive, but the rebellion against the puppet regime led to the third US intervention within months after the withdrawal. This time the US continued to occupy Nicaragua till 1933.

During this third intervention, the US helped create a military force, called the National Guard, in 1927. The National Guard was at the beginning commanded, equipped, trained and financed by the US. The chief of the National Guard, Anastaslo Somoza Gracia, seized power in 1936 and established a US backed family dictatorship lasting for almost fifty years (Weissberg, 1981). Under Somoza, Nicaragua acted like a true puppet of the US and, through the National Guard, provided counter-revolutionary military forces during the 1954 attack on the progressive Arbenz regime in Guatemala (which incidentally, profoundly politicised a doctor, Ernesto 'Che' Guevara, who subsequently led the Cuban revolution with Fidel Castro) and during the 1965 offensive in the Dominican Repubic. It was from Nicaragua, moreover, that the CIA mercenaries left for the 1961 Bay of Pigs landing in Cuba, the most concerted (albeit unsuccessful) US attempt to destory the Cuban revolution (Weber, 1981, p 30).

The Revolution: The third US intervention in 1925-26 inspired a nationalist uprising led by general Augusto Cesar Sandino. The war of resistance, fought on the lines of guerilla warfare, lasted till the murder of Sandino on 21st February, 1934. But it helped in radicalising many individuals who had been also influenced by the October Revolution. The 1959 Cuban revolution gave the struggle in Nicaragua further impetus and in 1962 the *Frente Sandinista de Liberacion Nacional* (Sandinista National Liberation Front, FSLN) was formed. The FSLN combined guerilla military warfare and rural and urban mass organisation and mobilisation for 18 years to lead the revolutionary insurrection on 19th July, 1979 that overthrew the Somoza regime, destroyed the erstwhile state power and created a completely new state apparatus under the leaderhip of the FSLN. It is under the leadership of the FSLN that the reconstruction of the Nicaraguan society is under way.

Before we take up discussion of the changes in the Nicaraguan health services after the revolution, it would be useful to know what role the health functionaries played in the revolution, although this aspect of the revolutionary movement is not very well documented. While the health care services have long been deficient in the Central American region, doctors, medical students and other health functionaries have participated in and even led struggles for social reform. Some examples can be given easily. Che Guevara in Guatemala, Calderon in Costa Rica, Romero and Castillo in El-Salvador, Bolanos and Rosales in Nicaragua and Morales and Alvarado in Honduras led political movements and governmental efforts toward the establishment of social security systems, workmen's compensation, the legalisation of unions, and agricultural reform (Garfield and Rodrigues, 1985). In Nicaragua, besides the above-mentioned doctors, reference can be made to a hunger strike by the health workers in the capital, Managua, in January 1979, in protest against the killing of dozens of people participating in a gigantic demonstration to mark the first anniversary of the assassination of Pedro Joaquin Chamarro, an anti-Somoza editor of the bourgeois paper *La Prensa* (Weber, 1981 p 4).

Post Revolutionary Health Services Reforms

Basic Principles

Nineteen days after the victory of the Nicaraguan revolution the new government issued a declaration outlining the basic principles of the new health care system. These principles are:

1 Health shall be a right of everyone;
2 Health services will be a responsibility of government;
3 The public will participate in health policy determination at all levels and
4 All health services will be planned on a regionalised, systematic basis, (Braveman and Roemer, 1985).

Special emphasis within the new system was put on maternal and child health, occupational health, and primary health care for everyone. To overcome the deficiency in the availability of health personnel, high priority was also given to producing them in much greater number and in a new mould.

Further, it should be kept in mind that these principles and new health care planning were inaugurated in the context of the thorough-going revolutionary reforms started in the entire social structure. The way the FSLN has introduced agrarian reforms, which undoubtedly have helped in improving the health status of the people will illustrate this point.

In July 1981, the first agrarian law was enacted which made it possible to confiscate land left lying fallow by owners holding 350 hectares or more of land on the Pacific Coast and 750 hectares or more on the Atlantic Coast. Another law enacted in early 1986 removed these limits of 350 and 750 hectares and has made it possible to confiscate land of all big landowners who do not plan for efficient production (Udry, 1986). The effects of these reforms can be seen in the fact that in 1978, 36.1 per cent of land was owned by those with more than 350 hectares, whereas they now (in 1984) own less than 11.3 per cent. The owners of more than 150 hectares of worked land, who possessed more than 50 per cent of the land in 1978, now have no more than 23.8 per cent. The land distribution has been carried through briskly. In the first fourteen months of the agrarian reform, the average rate of granting property titles was 647 per month, and the area of land involved was on average 15 hectares per family. In addition to the distribution of land for private cultivation, 38 per cent of land is under state ownership (APP 19.3 per cent) and co-operatives (10 per cent in Service Co-operatives, CCS and 8.7 per cent in Sandinista Agricultural Co-operatives, CAS) (Devilliers, 1984).

The contribution of these reforms to the improvement of the health status of the people cannot be underestimated, especially in a country which has a predominantly agricultural economy. Otherwise mere changes and improvements in health care delivery cannot achieve in seven years only, the tremendous improvement in the health status of the people. In short, what we are arguing for is not only that a revolutionary regime should seriously undertake thorough-going redistribution of wealth, but also that in order to make health a fundamental right of the people, people must be given the basic right over the means of production and the result of their productive labor power.

People's Participation

Another basic principle of the health services in Nicaragua is people's participation "in health policy determination at all levels". This term, 'Peoples Participation' is so much abused, particularly in the field of community health, that it must be put in a proper perspective in the context of Nicaragua. Fundamental to our understanding of people's participation is people's power—political and economic power in the hands of the working people, mediated through their own mass organisation and having decisive say in decision-making. Only if such people's power is existing can it get permeated in genuine participation of people in health care. Therefore, we must examine in brief whether these necessary pre-conditions for the genuine participation of the people, as envisaged in the basic principles, exist in Nicaragua.

The revolution in one stroke destroyed the essential part of the bourgeois state apparatus—its repressive forces—and created a new revolutionary army, called the Sandinista

People's Army (EPS), whose origin, composition, leadership structure and training was a *direct result* of the revolutionary struggle. The original police force was smashed and the Sandinista police was set up from working class fighters, thrown into unemployment because of war damage to the economy. In February 1980, the Sandinista People's Militia (MPS) was formed by arming tens of thousands of workers and poor peasants. The Sandinista Defence Committees (CDS) are another organised structure of the armed working people for their self-defence. While the EPS and the Sandinista police are part of the organised state structure, the MPS and the CDS are made of working people. The point to be noted is that the defence of the nation and exercise of power are not the functions of the state apparatus alone, but also of the armed volunteers from the urban and rural proletariat and the peasants. While discharging their duty as workers and peasants, the working people wield arms to fight against any attempt to take back the gains of the revolution. Therefore, even though the ruling classes are not completely expropriated—they continue to hold substantial economic power under the mixed economy—their *political* power is completely expropriated and any refusal by them to go along with the decisions taken by the revolutionary government is met with further expropriation, thereby deepening the revolution and consolidating the dictatorship of the proletariat.

Now let us see how these armed workers and peasants and even those who are not armed but come from the same classes have set up their mass and class organisations. We will mention five of them here: (1) the Sandinista Workers Confederation (CST) and (2) the Associaton of Rural Workers (ATC). The CST and the ATC are trade union organisations representing about 75 per cent of urban and rural wage workers. They provide an organic link by their constant cooperation and thus materialising the workers and peasants alliance. (3) The National Union of Farmers and Ranchers/Stock Rearers (UNAG) (4) The Luisa Amanda Espinoza Associationof Nicaraguan Women (AMLAE) (5) The 19th July Sandinista Youth (JS 19) (Udry, 1985).

The Sandinista democracy rests in the first instance on these mass organisations. Their power is not subordinated to any other abstract concepts. Further, although the FSLN commands political hegemony on the working people, it has not brought the Nicaraguan society under one party straitjacket. Instead, at the larger level it has opted for political pluralism and has legally allowed all political parties, both bourgeois and working class to operate, however, within the framework of new realities. In November 1984 elections, the opposition got 30 per cent of votes. This shows that Nicaragua has opted for a different type of political structure by allowing all political ideas to contend for hegemony within the dictatorship of proletariat and has thus chosen to face up to a series of problem that are relatively new in the history of the transition to socialism.

This is why a worker and a farmer in Nicaragua is not only a worker or a farmer, but also an armed defender of revolution, a soldier, and some of them even health workers and/or leaders of their mass and class organisations. Thus, the people's participation in health care is *an integral part* of people's participation and control over all the socio-economic processes in the Nicaraguan society.

Health Care under Somoza

Nicaragua is one of the poorest countries in the region with a population of thirty lakhs. In addition to poverty, illiteracy and ill-health, it faces a severe problem of structural unemployment. This is illustrated by the fact that the entire work force in Nicaragua grew only 6 per cent from 1961 to 1971. While the population aged 15 to 64 years grew by 40 per cent in the same period. This led to massive urbanisation with a large proportion of the population living in shantytowns (slums) on the edge of major cities. Roughly one-third (ten lakhs) of the country's total population is concentrated in its capital, Managua. This is one of the reasons why Nicaragua has 55 per cent of urban population despite the central role played by agriculture in its economy (Garfield and Rodriguez, 1985); 35 per cent of urban and 95 per cent of rural population lacked access to potable water (Halperin and Garfield, 1982).

As in any underdeveloped capitalist country, the official health statistics of pre-1979 Nicaragua are highly unreliable. Halperin and Garfield (1982) point out that "the Somoza regime paid so little attention to health matters that even such basic data as birth and death certificates were collected for only about 25 per cent of the population". The official estimate of the Infant Mortality Rate (IMR) was given as 35 per 1000 live births and was reported so in one of the WHO documents of 1980. A survey conducted in a part of rural Nicaragua in 1977, however, showed that the IMR in the sample population corresponded to an IMR of the order of 150 per 1000 live births (Heiby, 1981). Life expectancy at brith was 52.9 years. Indeed, Nicaragua had the lowest life expectancy at birth and one of the highest levels of the IMR in the region.

Malaria was a major public health hazard. Upto 60 per cent of the Nicaragua population had malaria during the 1930s. From 1934 to 1948, 22.4 per cent of all registered deaths were due to malaria. Upto 70 per cent of hospital beds were occupied by malaria patients during epidemics (Garfield and Vermund, 1983). The national malaria control programme was started in 1947 and was converted into an eradication programme, keeping with the change effected internationally at the behest of international agencies. According to Halperin and Garfield (1982), one-third of the people contracted malaria at least once in their lives. One of the important reasons for this high incidence of malaria was the indiscriminate use of insecticides in cotton and rice farming, leading to the Anopheles mosquito vector exhibiting resistance to all insecticides in common use, including DDT (dicophane), diedrin, malathion, propoxur and chlorofoxin. As a result in 1978 approximately 4.4 persons per 1,000 contracted this disease. The revolutionary civil war paralysed the health services and the incidence of malaria rose to 7.3 per 1,000 in 1979 and 9.4 per 1,000 in 1980 (Halperin and Garfield, 1982). This forced the Nicaraguan government to opt for, as an emergency measure, mass anti-malarial drug administration in 1981.

Besides malaria, tuberculosis and parasitism were endemic. Among the top ten killers of children were diarrhoea, tetanus, measles, whooping cough and malaria. Some of the major causes of death in 1973 are shown in Table 1:

TABLE 1

Causes of Death	Death Rate per 100,000 population (1973)
1. Infectious and parasitic diseases	141.8
2. Diarrhoeal diseases	97.0
3. Pneumonia and influenza	190.5
4. Avitaminosis and other nutritional diseases	2.1
5. Homicide and war	24.0
6. Poorly defined causes	151.8

Source: Garfield and Rodriguez, 1985.)

Some studies in malnutrition have estimated that between 46 and 83 per cent of Nicaraguan children were malnourished. The same studies have indicated that a high proportion of these children (25 to 45 per cent) had the more severe secondary and tertiary types of malnutrition (Halperin and Garfield, 1982).

Health Services: A decade before the revolution four separate agencies and independent health ministry offices in each province ran in Nicaraguan health system. All four agencies and provincial officies of the health ministry functioned independently without any coordination. The ministry of health had the main responsibility for rural health care.

For the salaried population, the Nicaraguan Social Security Institute (INSS) was established in 1957. Twenty years later it served only 16 per cent of the economically active population and only 8.4 per cent of the country's total population. (Garfield and Taboada, 1984). Several churches ran highly respected hospitals, but for the most part they treated only those who could pay cash. The National Guard had relatively good medical services, including most specialities, through a system of hospitals and clinics of its own.

Health Expenditure: Of all the expenditure in the health sector, the INSS commanded 50 per cent, the ministry of health only 16 per cent and other local agencies, charitable and private insurance groups the remaining 34 per cent (Garfield and Taboda, 1984). This way, a great divide was created between a tiny minority of insured salaried workers (mainly white collar government employees) and the overwhelming majority of non-insured. Preventive care was neglected, save for some disorganised attempts in respect of malaria. All of the INSS and much of the ministry's budget was devoted to curative care. Of the approximately 13 dollars per capita spent in Nicaragua in 1972 by the health sector, only about 3.15 dollars went for preventive care (Garfield and Taboada, 1984).

Health Personnel: The Somoza dictatorship considered students, especially in the health professions, a potentially subversive group and tried to limit their number. Thus, Nicaragua had only one medical school with 73 students in a class. The total number of doctors was 1,300 and there were only 43 professional nurses per 100 doctors. Not surprisingly, 80 per cent of rural health manpower consisted of folk-healers. We do not have any information about their indigenous medical practices and what the revolutionary government is doing about it.

An official community health experiment was carried out in Nicaragua from 1976 to 1978. In this programme, 768 *parteras* (traditional birth attendants) were trained in six-day courses, to carry out in their community improved obstetrical care, treatment of diarrhoea in children using packets of oral rehydration salts, provision of contraceptives, provision of aspirin for fever and pain and so on. A trained *partera* was given a free health kit [illegible] was required threafter to purchase supplies through the local government clinics. At the end of the experiment in 1978, about 40 per cent of the *Parteras* had already dropped out (Heiby, 1981). The government was so disinterested in the programme that it did not make any serious effort to keep it going nor did it carry out any follow-up work.

Thus, what the revolution inherited was poverty ill-health, unemployment and rickety health services. In addition, it also had to (1) care for the families of the 50,000 dead in the civil war and the 100,000 wounded people and their families, and cope with (2) considerable destruction of industry (Somoza bombed his own industries to thwart revolution), disorganisation of two agricultural cycles with repercussions on food supplies and exports (GDP per capita had declined to levels of 17 years before), a massive foreign debt, a near-total lack of foreign currencies and high inflation, (3) a poorly developed economy (much less developed than Cuba in 1959), (4) dependence on agro-exports for earning foreign exchange, and (5) the ever-present threat of economic sanctions and even of a blockade (Fourth International, 1985).

Post-revolutionary Reforms

Many persons mistakenly think that immediately after the proletarian revolution, the revolutionary regime brings under state ownership *all* the means of production and services. Actually, while the state takes upon itself the responsibility of providing adequate health care, it does not do so by any such overnight take-over of the services. The seizure of state power and the nationalisation of the core of the economy can be timed by the day of the insurrection, but the actual consolidation of the revolution takes place in course of time, by a process in which the continuing class struggle within the country and internationally plays a prominent role. Even decades after the revolution in these countries, small-scale private producers (artisans, private medical practitioners, small capitalists, etc) are not completely expropriated. They survive as a marginalised sector and under restrictions. Therefore, an attempt to characterise a revolution in its initial years only on the basis of the proportion of the state-owned economy and services could lead to wrong conclusions. What is decisive is the ideology and class nature of the revolution's leading organisation, the actual role played by the new state in the ongoing class struggle—does the state side with workers and farmers? Does it expropriate those propertied classes who go against the people's interest?—and the development and extension of the workers' and farmers' power and control over all aspects of the new social structure.

The continuing presence of private sector in the economy thus does not disprove the proletarian character of the revolution, although such a sector does have subversive potential. This makes it more imperative for the revolutionary state to deepen the class struggle. The state of reform of the health care system in Nicaragua is also at this stage only. Although the state has undertaken full responsibility for providing health care (see basic principles cited above), and it has achieved astounding success in improving health care, this has not been done by sweeping abolition of the private sector and private practice. The trend, however, is clear. The state is for people's health care. Those health personnel who want to continue in the old way of looting people, will not be allowed to do so. First restriction and then, if necessary, expropriation.

Health Structure: Immediately after the revolution, the previously separate health agencies were integrated within the Ministry of Health (MINSA) and a United National Health System was started.

Doctors' Response: Nicaragua had one medical school in Leon and a second one was opened in Managua in 1981. By 1983, 2,240 medical students were undergoing training in these schools, an increase by four times over the 1978 level (Braveman and Roemer, 1985). Unlike in the case of Cuba, only about 300 of the total 1,300 doctors left the country due to the revolution. This was largely because private practice was allowed. Before the revolution, about 65 per cent of the doctors were paid for some public service, but for most of them this constituted only a few hours a day and the rest of the time they were engaged in private practice. After revolution they were pressurised to fulfill their contracted time and increase their scheduled public practice to at least six hours a day. Their salaries were standardised (Garfield and Taboada, 1984).

After revolution, the doctors' official organisation Federacion de Sociedades Medicas de Nicaragua (FESOMENIC), which is a leader of the Federation of Professional Organisations (CONAPRO) and has the backing of the propertied strata, increased its political activities. In 1980 when the government started discussing a law to regulate professional activities, it opposed it tooth-and-nail. It organised a one-day walk-out and even threatened mass emigration to Miami. The government retreated by making the law less specific. Nevertheless, the government passed the law and for the first time made the doctors and other professionals accept the government's right to regulate their professions. This tussle at the same time divided the professionals into the progressive and the conservative camps and in July 1981 a formal split took place. The progressives could maintain official recognition and this ultimately forced the consertatives to rejoin the organisation (Garfield and Taboada, 1984).

Personnel and Training: International assistance has greatly helped Nicaragua to fill up deficiencies in the number of personnel. There are about 800 foreign health workers in Nicaragua, coming mainly from Cuba, Latin America and Western Europe. Cuba and the Pan American Health Organisation have also greatly assisted in teaching programmes.

A complete overhauling of the medical curriculum has been carried out since 1979. The new six-year course consists of clinical service, teaching, administration and research. For imparting such integrated medical training, 'work-study programmes' are instituted wherein the student is required to assist from the outset in supervised public education projects, in community surveys to asses health needs, door-to-door programmes to give immunisations, serve as an administrative assistant in local public health offices, etc. The student is also placed in work settings to learn about occupational health and in outpatient settings to learn about preventive maternal and child health services. On the other hand, the clinical rotations are almost always hospital-based, thus creating a discrepancy between the primary care goal and hospital based training practices. This discrepancy is increasingly being questioned by the teachers and students (Braveman and Roemer, 1985).

Nicaragua has six nursing schools with five times the pre-1979 enrolment. The educational qualification required for enrolment has been drastically lowered. For Auxiliary Nurses the person should only be literate and ten months' training is given. Technical Nurses require primary school education and are given two years' training. While professional Nurses require secondary school graduation and are given three years' training (Braveman and Roemer, 1985). At this rate it is certain that Nicaragua will correct the present adverse nurse-doctor ratio very rapidly.

One of the earliest programmes started by the MINSA was training paramedical health aides, called *brigadistas*, who were selected from the youth organisations. They received several months' training and were sent to isolated rural areas. They were to serve for at least two years after which they would be eligible for professional training. In fact many of them went on to become health educators and medical students. The doctors forcefully opposed this programme and so it was revised: The revised programme took up mobilisation of a large number of people in the immunisation, malaria prophylaxis and sanitation campaigns which were launched in 1981. The campaign included a short-term training course and public health education. It is estimated that upto 10 per cent of the country's population was mobilised as health volunteers in these campaigns. The class and mass organisations listed earlier in this article actively participated and provided volunteers. They also promoted the formation of local, regional and national community health councils which are now active throughout the country (Garfield and Taboada, 1984).

But a campaign means a programme that ends at one point of time. This is not allowed to happen by converting the activity into permanent work by providing extensive training to a section of the volunteers. There are now 25,000 of these permanent but volunteer *brigadistas* comprising about 1 per cent of the total population (Garfield and Taboada, 1984). This supports our earlier contention that many of the workers and peasants are armed defenders of the revolution and also health workers. People's participation is not a cosmetic exercise, but is elevated to self-activity by the people to decide the condition of their lives.

Achievements of the Campaigns: As mentioned earlier, during and after the civil war, the incidence of malaria increased so much that there was no alternative but to take

up mass campaigns to bring it under control. The government opted for Mass Drug Administration (MDA) in 1981. Three ambitious goals were set: (1) to prevent new cases, (2) to cure subclinical cases, and (3) to reduce the transmission. For this purpose, 70,000 voluntary workers, *brigadistas*, were trained. These volunteers recruited many helpers. A malaria census was carried out in which 87 per cent were covered. The drugs were given to an estimated 19,00,000 people. More than 80 lakh does of chloroque and primaquine were distributed in October 1981.

As a result, the total number of malaria cases fell considerably from November 1981 to February 1982. However, the incidence of P.Vivax cases returned to endemic level by March 1982, while that of P.falciparum stayed below endemic level for three more months. The net result was that if we take the average of the previous two years' incidence rates as the baseline, there were 9,200 fewer cases of malaria than expected during the four months of reduction in general incidence. It is clear from this that the objectives of prevention and cure of malaria infection were better realised than that of reducing transmission, as the MDA could not reduce transmission to a 'break point' below which malaria eradication could occur (Garfield and Vermund, 1983). This shows that even such a massive exercise could not realise the theoretically possible decisive break in the chain of infection.

Compared to this moderate success of the MDA campaign, the *immunisation campaign* was a resounding success. BCG vaccinationis given at birth, and the three-fold increase in coverage since 1980 reflects a huge expansion in maternal care. Diptheria-pertusis tetanus (DPT) immunisation is given at health centres and health posts as part of routine child growth and development services. The DPT coverage is increasing at an average rate of 30 per cent per year. However, this increase is not so spectacular. Measles vaccination reches 60 per cent of children in the first year of life and 85 per cent before their sixth birthday (Williams, 1985).

The key to this success in immunisation is a mass campaign through holding regular 'health days' all over the country. For health days, 20,000 volunteer *brigadistas* have been trained in vaccination, health education, etc. On health days vaccinations are done between 7 am to 6 pm with schools, community buildings and health facilities as assembly points finishing with a house-to-house sweep through the neighbourhood. The results are announced through mass media (Williams, 1985). Table 2 shows the immunisation coverage.

TABLE 2: ESTIMATED IMMUNISATION COVERAGE OF CHILDREN UNDER 12 MONTHS

Immunisation	Percentage Coverage in	
	1980	1984
BCG	33	97
DPT	15	33
Poliomyelitis	20	76
Measles	15	60

Source: Ministry of Health and UNICEF Office, Managua (as given in Williams, 1985).

Health Financing and Facilities: Government funds directly related to the provision of health care jumped from 200 million *cordobas* in 1981 and reached an estimated 1,593 million *cordobas* in 1983. In 1981, the government budget for health was 12 per cent of all public spending (Garfield and Taboada, 1984).

In the last months of the revolutionary war, Somoza's National Guard destroyed four hospitals, seriously damaged five others and looted four more. Post-revolutionary reconstruction has now provided 18 hospital beds per 10,000 population. There are 4,829 hospital beds in Nicaragua, but greater awareness and accessibility has increased their use. Five hospitals with 1,078 beds are under construction (Garfield and Halperin, 1983). To tackle problem of diarrhoea, especially in infants, the government initially planned 170 rehydration centres, but popular demand and people's action have brought 226 such centres into existence (Halperin and Garfield, 1982). The availability of health services has increased tremendously. It is estimated that more than 80 per cent of the population now has some regular access to medical care (Garfield and Taboada, 1984).

Health Condition: Finally, about some overall achievements. The IMR has got reduced to 80 per 1,000 live births. No case of polio has been reported since 1982 despite an epidemic in neighbouring Honduras in 1984. Only 3 cases of diptheria were reported in 1983. Neonatal tetanus, however, still remains a significant problem (Williams, 1985).

In short, the reforms in health care in Nicaragua show people's determination to collectively change society. The future of the revolution is, however, not fully secure and is threatened by internal and external dangers. This has happened to all such revolutions. The Soviet Union was invaded by several countries to destroy the Bolshevik Revolution; Cuba had its Bay of Pigs invasion; Vietnam had to fight for decades for survival; Grenada was overpowered; Nicaragua has been assaulted by the CIA sponsored contras and a partial blocade since 1981. The very fact that it has achieved so much under conditions of a threat to its very survival and continous war since 1981 shows the revolution's lasting power, the new state's mass base and the preparedness of the working masses to sacrifice to preserve the gains of the revolution, including the gains in health and health care. Nevertheless, the war has its impact, and such protracted aggression has consequences for people's health. Epidemiology of war is an emerging subject and the war on Nicaragua has made it much more relevant. Health professionals will have to understand it more and more for the world is likely witness more revolutionary upheavals, revolutionary crises, and imperialist aggressions.

Health Consequences of War in Nicaragua

The Central American countries are under the grip of violence, more so since 1980. Violent death is the most common cause of death in El Salvador, Guatemala and Nicaragua since 1980. At least 40,00 people have been killed by military and death squads in El Salvador (population 47 lakhs) and many more have been killed in bombing and other attacks. It is estimated that 20,000 Gautemalans (population 41 lakhs) most of them indigenous tribes, have been killed by the army in the last three years. The war takes a toll mainly

of young men. This is illustrated by the fact that although life expectancy at birth among Salvadoran women has risen steadily, reaching 67.7 years in 1980, it fell remarkably for Salvadoran men from 58.4 years in 1978 to 52 years in 1980. More than 1,20,000 Central Americans have died from war-related causes since 1978. This amounts to a 10 per cent rise in mortality above expected levels during this period. It is estimated that more than a million Central American live as refugees within the region and a million have fled to America (Garfield and Rodriguez, 1985). This is how imperialism is trying to crush the hopes and rebellion of people in Central America, who have been inspired by the Nicaragua revolution. The effects of imperialist aggression on Nicaragua are no less tragic.

More than 100,000 persons were wounded in the revolutionary war in Nicaragua and 50,000 lost their lives. After the revolution, the CIA-backed contra attacks have, between January 1980 and January 1986, killed 3,999 persons, wounded 4,542 persons and 3,791 persons have been kidnapped. In 1985 alone, 1,852 persons' were wounded, 1,463 were killed and 1,455 kidnapped, indicating the counter-revolutionaries who have been killed in the armed conflicts—they are also victims of US aggression—the number of casualties totals 23,822 persons including 13,930 dead (Ortega, 1986). The president of Nicaragua, Daniel Ortega, in his recent speech to the National Assembly said that the total number of people killed as a result of the US policy of terrorism against Nicaragua would be equivalent, as a proportion of the population, to some 1,03,000 dead for the US (Ortega, 1986).

Ortega also gave information about other losses:

1. In 1985, aggression increased Nicaragua's balance of payment deficit by 108 million US dollars, the trade deficit rose by $ 89 million and the capital deficit by $ 19 million.
2. A total of 120,324 people have been displaced from their lands by the war, of these, 33,000 have been relocated to 55 urban and rural settlements.
3. Health services to 250,000 people have been impaired due to the damages caused to 55 health units, including one hospital and four health centres.
4. 48 schools have been destroyed and 502 other education centres can no longer operate because they are located in war zones; as a result, a total of 60,240 elementary and 30,120 adult education students are no longer able to attend classes.
5. In the area of social services, the mercenaries have destroyed four rural child care centres, three nutrition centres for children and two offices of the Nicaraguan Social Security Institute. This has directly affected services to 2,222 children and elderly people.

The strength of the Nicaraguan revolution lies in people's power and in its accomplishments in the fields of health, education (the revolution's strategy of imparting education to all has been most successful), nutrition, employment, etc. The counter-revolutionary contra mercenaries know this. Hence health and educational centres and health functionaries are made special targets of attacks. At least 22 health workers (including two European volunter physicians), medical students, nurses, malaria control workers, health educators and vaccination campaign workers have been killed while delivering health care (Siegel *et al*, 1985). Garfield (1986) puts the number of health workers killed at 31. In terms of availability of health facilities, as the Nicaraguan Health Workers Union (FETSALUD) reported to visiting American physicians, the increase the in the number of civilians and soldiers wounded in the war has strained existing health facilities, leaving less resources for normal civilian needs (Siegel, 1985).

Further increase in the health budget has been suspended due to increase in military spending, the budget for which increased from 18 per cent in 1982 to 25 per cent in 1984. Not only that, 20-25 per cent of Managua's health workers are at the war front, actually fighting with arms and many of them are getting killed. This has necessitated training of new health personnel.

The economic embargo on Nicaragua by the US has devastating consequences for health care. Immediately after the revolution, there was a crisis in the availability of pharmaceuticals. The foreign drug companies wanted the debt incurred by the Somoza government to be settled before sending any more drugs. The Sandinista government had to accept responsibility for the debts in exchange for favourable terms of repayment (Halperin and Garfield, 1982). Another major problem is the lack of spare parts for medical equipment. Much of the machinery is made in the US, but shortage of US dollars as a result of the war makes acquisition of replacement parts difficult (Siegel, *et al*, 1985). Thus, when equipment breaks, it may remain out of commission or one piece of equipment must be cannibalised to fix another (Helperin and Garfield, 1982).

In 1983, agricultural losses directly related to the war totalled 10 million dollars. Since 1981, total destruction related to health has been valued at over 70 million dollars (Siegel, *et al*, 1985).

Effects on Diseases

The term 'epidemiology of aggression' was first used by a group of doctors connected with Regional Leishmaniasis Group in Nicaragua, to analyse health data ascribable to the US aggression in 1982. Before 1979 leishmaniasis was known to exist in Nicaragua but was not reported to the WHO. After the revolution reported cases increased and came to ocupy the fifth rank among all notified infectious diseases. When the Leishmaniasis Group started a study of this disease in 1982 in one region, the study was violently interrupted after 24 hours by a contra attack in which several people were killed, including Dr. Pierre Grosjean, one of the two European volunteer physicians (Morelli, *et al*, 1985).

One aspect of the epidemiology of war is *the impossibility of obtaining basic data*. Cases registered in this region progressively increased from 1980 (143 cases) to 1982 (2,107 cases); since 1982, with the intensified war activities, the number of notified cases fell to 1,054 in 1983 and 806 in 1984. This is not due to actual decrease in number of cases but due to destruction of facilities, less access to services and migration. Another aspect of this epidemiology is related to troop movements. Non-immune people have the clinical manifestations when they enter, in troop movements, the natural environment of leishmaniasis. This can be seen from age-sex distribution: the significantly high incidence usually seen in under 5s has shifted to appear in males aged 15-30 years. The third aspect is related to migration. People living

in endemic areas often resettle, because of the war, in non-endemic areas, resulting in the first appearance of the disease in those zones. Thus, as the Leishmaniaris Group puts it, in the war-affected northern regions of the country, aggression and leishmaniaris, indeed, coincide 'epidemiologically' (Morelli, 1985).

Before we conlude, a mention should be made of the psychological effects of war. The Americans, for instance still suffer from the psychological effects of the Vietnam war and a numbr of studies are still being carried out to assess the increased number of vehicular accidents and suicides amongst Americans who were drafted to fight for US imperialism in Vietnam. As reported by Dr. Felipe Sarti, the chief psychologist at a psychiatric day centre in a poor suburb of Managua, approximately 25 per cent of all patients show depressive illnesses connected with the war. This depression is particularly prevalent among parents and siblings of soldiers who have been killed or sent to the front (Seigel, *et al*, 1985).

The US sponsored aggression is still continuing and no end to it seems likely in the near future. Such a situation can jeopardise the revolution in the long-term. This annihilation of revolution must stop. The US administration knows that if it opts for direct intervention, it won't be any cakewalk. The working masses are armed and they will fight till the last person. And hence this new strategy of protracted aggression combined with economic harassment and internal sabotage through the still-unexpropriated big strata of the former ruling classes. The danger is real. If a massive counter revolutionary attack is mounted by all of them it will have a chilling effect on the revolutionary movement all over the world. Even if such an attack fails, there are bound to be major distortions in the revolution. Its democratic fermen. may get lost. A massive bureaucratic state apparatus may emerge and with the best class-conscious workers and peasants dead in the war, such an apparatus can get consolidated. International solidarity is a need of the hour.

Many health professionals have reacted with revolutionary zeal to this need. Today, over 900 internationalist health workers are helping the revolution. They are from Cuba, Latin America, Mexico and Europe. Many more can and should join. If we allow imperialism to roll back this revolution, as it did in Grenada, history will not forgive us. No matter how strong the justification for localist thinking and local-based activity, this international defeat will affect all of us sooner or later. We must say, "Imperialism—hands off Nicaragua".
